The history of Javanese Cinchona culture in the successive stages of development is related with rigid simplicity, and the translator has done excellent service in placing the results of the energetic director's labours before English readers.

Mr. Van Gorkom treats by chapters the early history of Cinchona, the botanical description, culture, administration, commerce and trade, harvesting of bark, diseases and enemies, quinine alkaloids, and financial success of the undertaking. The cultural details are described very fully, and the only fault we have to find with the work is the too great fidelity with which the translator has adhered to the Dutch idioms, which are sometimes inelegant and wanting in clearness of diction. There are some errors of the press, probably arising from the book being printed in English at Amsterdam. A chart, showing the relative position and elevation of the various plantations in the island, would have been very useful. A copious index helps the reader to find everything he requires. We regret the high price (40*s.*), which will doubtless impede the usefulness of the book by checking its circulation. Dr. King's admirable Manual of *Cinchona Cultivation in India*, prepared with great care and ability, can be procured in Calcutta (2d edit., 1880), we believe, for a fractional part of the money.

At p. 18 the labour question is alluded to, and it is interesting to note that, whilst the culture was for some years performed by paid statute labourers, and supplies of material ordered by the Government, since 1865 the Cinchona culture has become a wholly free undertaking.

At p. 87 we observe—"The best plants were *always* obtained from seeds sent to us from South America or British India," implying that seeds harvested from other countries often succeed better than those of indigenous growth; and at p. 157 this practical cultivator, the McIvor of the Dutch Netherlands, insists strongly on "keeping the young plantations absolutely clean," while he considers "deep pits altogether unnecessary when the soil is deeply stirred.

In the chapter on the harvesting of the bark we find:—

"For years the Government Cinchona undertaking has been an experiment on a large scale; the fixed rules and systematic methods, the fruitful sequence of this, come chiefly to the profit of the private planters who are travelling on this road by help of the Government."

"Whether thin or close planting be adopted, in both cases a time comes when the original planting requires thinning, and then for the first time a crop is reaped, which at the same time tends to improve the planting. At the first thinning the choice has to be made between uprooting or felling to the stump."

"Another method can be applied to the remaining trees; they are standing at sufficient distance, and will soon offer stems of considerable dimensions. Upon these can be tried the plan already mentioned of partial stripping or shaving. So also attempts may be made to enhance the amount of alkaloid by temporary covering (one year or longer) with moss, or other materials at hand."

There appears to be considerable force in the following remarks (p. 191):—

"We have a prejudice against partial barking—stripping, as the English call it—that is, the cutting out of long strips of bark. The trees may bear the operation well enough if it be done with care; but they are none the better for it, and as soon as it is applied on a large scale, the labourers cannot be kept under strict supervision, and therefore the chances of damage to the trees are considerable."

In the Nilgiri plantations the mossing process for renewing bark was perseveringly followed by the late Mr. McIvor, chiefly on Cinchona succirubra trees. In Java, Herr Moens, the Government Analyst, appears to have followed up McIvor's practice with zeal, but quickly remarked that the virtue did not consist in the moss itself. He substituted the fibrous sheaths of the Areca* Palm with an entirely satisfactory result. Again, in 1880, he covered the exposed bark with wild grass (Imperata arundinacea), used as forage; this was also successful. The conclusion arrived at is that the character of the alkaloids remains in the renewed bark the same as in the original, only the quantitative proportion changes, and that the result is not the least dependent on the nature of the covering material used.

In 1879, Moens advised the treatment of Cinchona Ledgeriana by outside scraping (shaving) of the bark, and the highest price was realised for the scrapings; the term has been abandoned, and scales (*schilfers*) is now given.

It may be noted that in the last report of the Madras Cinchona Plantations (1881) the Javan slicing or scaling system has been under trial, and the scraped red bark from Neduvatan realised a fair price, but the effect of the process on the trees is said to have been injurious, and McIvor's mossing system is still preferred.

"Hasskarl was the great executant of the Dutch plans. Markham fulfilled that task for England on a greater scale, but also better prepared, and with ampler help. McIvor, Anderson, and Thwaites were by Markham and his coadjutors put into position to lay the foundation of a culture which in twenty years' time may acquire an unimaginable significance and extent."

"If rivalry has prevailed between the English and Dutch directors of Cinchona culture it has in no sense harmed the development of the latter; the most cordial co-operation on both sides continues undisturbed. Impelled by international interest it was held to be a principle of humanity."

The statements of the capital and revenue accounts of the Government Cinchona plantations from the commencement up to date show a substantial balance in favour of Government both in India and in Java.

It is pleasant also to notice how cordially the two Governments have co-operated in the interchange of seeds and experience in advancing this, the greatest cultural undertaking which the world has ever witnessed.

In the latter part of 1880 Bernelot Moens, the new Director of Culture in Java, visited Ceylon, Madras, and Bengal. He had excellent opportunities of comparing the results obtained in these various fields of experiment, and we understand that a complete report of his impressions and observations may be shortly expected, which will doubtless be of great value both to planters and men of science.

It may here be be added that Mr. Lawson (late Professor of Botany in the University of Oxford) started on Thursdaylast to assume charge of his new appointment as Superintendent of the Government Cinchona Plantations, Ootacamund, where his scientific knowledge of plant-growth should serve him in good stead.—*Gardeners' Chronicle.*

* A *Handbook of Cinchona Culture*, by Karel Wessel van Gorkom, formerly Chief Inspector of Cultures in the Netherlands East Indies; translated by B. D. Jackson, Secretary, Linnean Society. Pp. 292, 4 to. London and Amsterdam (Trübner), 1883.

THE FIG TREE.†

During a lengthened stay in Naples and attendance at the Zoological station of that city, Count H. zu Solms Laubach, assisted by Dr. P. Mayer, one of the staff to the institute, and by Baron Valiante, made a special study of the origin, domestication and cultivation of the fig-tree (*Ficus carica*, L.), the result of which he has published in the form of a pamphlet, 'Die Herkunft, Domestikation, und Verbreitung des gewöhnlichen Feigenbaums. Von H. Grafen zu Solms-Laubach. Göttingen, 1882.' The work is especially devoted to the study of the history of the fig-tree, and the operation of caprification, which, as is known, consists of hanging the fruit of the wild fig upon the cultivated tree, receives considerable attention. Perhaps it will be as well to mention here, for the benefit of some less acquainted with the subject, that the fruit of the wild fig is hung upon the cultivated tree by gardeners, in order that the insect which

* Not *areca* but *arenga*.—Ed.

† From the "Daily News."

lives in the wild may enter the cultivated fruit, which they think results in preventing the figs from falling off, hastens their maturity, and improves their taste. Count Solms-Laubach begins by mentioning that already in ancient times two distinct varieties of fig-trees were clearly distinguished, the fruit of the first of which is sweet, succulent and eatable, that of the other remaining hard and milky until it attains a very imperfect maturity, without the least formation of sugar, and then quickly dries up. Count Solms-Laubach distinguishes the first species by the name of fig-tree, the other by the name of caprificus, or as it is called in the Neapolitan dialect, "profico." The caprificus (or wild fig-tree) usually bears fruit thrice, the cultivated fig-tree twice a year. The caprificus in the interior of its fig has both male and female flowers; the fig-tree usually only female. It is the female flowers of the caprificus fig which contain the insects that serve for the operation of caprification. Both the caprificus and the fig-tree are obtained from sowing the seed of the cultivated fig; but as the quality in such cases is generally very bad, propagation is exclusively carried on by shoots. The curious insects developed in the caprificus flowers, and called *Cynips Psenes* by Linnæus, but now named *Blastophaga grossorum*, were already known to the ancients as a means of caprification. These insects belong to the order of Hymenoptera. The females are winged, the males wingless. In Naples, where the author made the greater part of his studies, the wild figs produced at different seasons of the year are respectively named "mamme," "profichi," and "mammoni;" and it is from the first of these, the so-called mamme (which are the earliest harvest of the caprificus and ripen in April), that the insects which have wintered therein issue in spring in order to lay their eggs in the fruit of the second harvest, the so-called profichi, which ripen in June. When this has taken place—a very few insects, thanks to their great productiveness, are able to fill numerous flowers with their eggs—the mother insects die; in May the larvæ, and in June the perfect insects are formed, and meanwhile the fruit of the third harvest, the so-called mammoni, which ripen in August and September, are ready to receive the female Blastophagæ. From these mammoni, finally, the brood wanders into the mamme in order to winter, and thus the chain of events is completed, and in the following spring the laying of eggs in profichi is recommenced. Let us now see what happens when the female Blastophagæ, instead of entering the figs of the caprificus, lay their eggs in those of the cultivated fig-tree. The insects, indeed, perform the operation, but are unable to lay their eggs in the proper place (for reasons shown in the pamphlet, but too detailed to be mentioned here), and the progeny, therefore, never develops. Nevertheless the entrance of the insects has a most important influence; they carry with them into the fig with exclusively female flowers the pollen of the male caprificus flowers, and thus cause the formation of seed. Our author describes the Blastophaga as a small black insect issuing between the scales of the ripe fruit in June. Having arrived outside, it suns and dries its wings, and cleans its hairy body with its feet to rid itself of the pollen which adheres to it so thickly that it looks as if powdered. If one opens a wild fig at the proper time, a large number of these insects are seen running about, evidently seeking to escape. The wingless and helpless males are distinguished by a bright amber colour. When the insects penetrate the figs of the young profichi to lay their eggs, they frequently lose their wings, so great is the effort needed. Count Solms-Laubach often found whole bunches of torn-off wings, where many females had entered the same figs. They generally die after laying their eggs, while seeking their way out. Opinions are divided as to the efficacy of caprification. By some it is considered advantageous, while others regard it as injurious. Count Solms-Laubach gives his verdict as follows:—"Caprification is an operation, traditionally preserved from generation to generation in the same form, which, once necessary, is now scarcely useful, but the scientific importance of which as a means of determining the changes experienced by our cultivated plants in the course of years cannot be too highly valued."

After deciding the geographical extent of the cultivation of the fig-tree, the author calls attention to the curious fact that caprification is not always practised where the insect is found. In Greece and its islands, in Sicily and Naples, in Southern Spain and Portugal, in North Africa and Syria, and Asia Minor, it is generally introduced; but is not practised in middle and North Italy, the Tyrol, Sardinia, Corsica, the South of France, Northern Spain, the Canaries and Azores, nor in Egypt. Fossil remains prove that the *Ficus carica* was spread over the whole Western portion of our present civilized world in pre-historic times, and that it existed also in Greece and in Asia Minor cannot be doubted, in spite of insufficient proof. In France the quaternary district in which it existed exceeded in extent the present district of cultivation. The author believes, with Lloyd, that the fig-tree had died out in the whole of the Western world, and was only reintroduced in the progress of civilization. He finds the different species so similar that a common origin cannot be doubted. Western Asia and North Africa are named as the fatherland of this origin, but without sufficient proof. The author comes to the conclusion that the fig-tree had an equatorial fatherland, in contrast to the circumpolar fatherland of the vine, and finds the most favourable conditions for such an origin in the Punjaub, Beluchistan, and South Persia, as well as in the border terraces of Abyssinia. From the circumstance that probably the invention of caprification will have gone hand-in-hand with the domestication of the fig-tree, and that the former operation is carried on now exactly as it was in ancient times, and also because the nation which invented caprification must have been tolerably far advanced in civilization, the author believes that the cultivation of the fig-tree commenced at a single point, and thence spread to the rest of the world. To which nation, then, do we owe it? It is proved by ancient authors that the domestication of the fig-tree was known in Greece in the ninth century, B.C. The Bible, and especially the Semitic name of "ti'n," a word belonging to the dialect of the Bahra race, leads us to Arabia as the mother-land of domestication and thence probably it spread to the Semitic peoples of Syria. These commercial nations having once possessed the tree, it was natural that its cultivation should spread. The Greeks will have received it from the Phœnicians, as probably also will North Africa, Southern Portugal, and Spain, Sicily and Malta; and many facts speak for such a direct introduction. In Italy we find the curious circumstance that caprification is practised in the south, but not in the north. The contrast was so great that even in the eighteenth century the North Italians were not aware that their southern countrymen made use of caprification. Count Solms-Laubach comes to the very interesting conclusion that the Romans received the fig-tree direct from the Phœnicians (of which the name *Ficus* is cited as a proof), but only the tree and not the practice of caprification was known to the Semitic races; while caprification was independently introduced into South Italy by the colonizing Greeks. The last chapter of the pamphlet is devoted to a short study on the sycamore (*Sycamorus antiquorum*, Miq.), to which the author's attention was drawn by the many analogies between that tree (in the fruit of which similar insects are found) and the fig-tree.—*Pharmaceutical Journal.*

JUDICIOUS PRUNING.

Mr. William McCorquodale, Scone, read a paper [at the annual meeting of the Arboriculture Society] on "Judicious Pruning more especially applicable to Oak Plantations." He said:—

It is, however, much to be regretted that there are so many conflicting opinions on this subject. Some authors strongly recommend the advantages of skilful pruning; and others positively deny that any advantage will accrue from even judicious pruning.

In the English Crown Forests pruning was abandoned some thirty years ago; and, following that example, the same result has since taken place on many private properties in both England and Scotland.

Some theorists declare that there is such a direct subsistence between the roots and branches that when a live branch is removed, all the corresponding roots supporting that branch will immediately thereafter cease to perform their functions and will die.

I well remember, nearly forty years ago, having a very interesting conversation with an able arboriculturist on the subject of pruning, when he substantially denied that the art of pruning in any shape or form would do good.

He maintained that when a live branch was pruned off a tree, the roots in the ground supporting that branch would die. After a considerable amount of discussion, I asked him to give me a satisfactory answer to one question in support of his theory and I would be satisfied. That question was, "Why is it that when a healthy oak tree is completely cut at the surface of the ground, the roots do not die; whereas, on the contrary, the roots continue in vigorous action, and immediately thereafter the stool produces a healthy crop of oak shoots." On hearing this, instead of answering my question he was speechless, and walked off.

Shortly after this, I resolved to try experiments to enlighten myself on this subject by sowing a few seeds of the *Pinus Douglasii* in a convenient corner in my garden where I could make a daily inspection when necessary, to see if I could make any satisfactory discovery relative to the subject of our discussion. From these seeds I reared one plant for four years till it was about three feet in height.

During the whole of that period I never allowed even a bud to form on the stem of this plant. So soon as one appeared it was at once rubbed off. The plant, notwithstanding, grew with a beautiful clean, straight stem; but, unfortunately, in the fourth year of its growth, in autumn, when the hedger was engaged cutting the garden hedge, he accidentally broke it over near the surface of the ground. However, it answered my purpose very well. I grubbed up the root carefully at once for inspection, and to my agreeable surprise the root, as a whole, was unusually large for a plant of its size, seeing that it was never permitted to produce the semblance of a branch.

The root was divided into three large forked ones, and each of these was matted with healthy fibrous rootlets at their extremities. From my friend's point of argument, I fully expected that this plant, which was reared branchless would have no other root but the tap-root; but I found no difference in the ramification of its roots, from that of young plants of the same age, having their whole natural branches.

I shall add only one other illustration on the connection subsisting between roots, branches, and stools of trees, which, together with the foregoing remarks, will, I trust, go far in demonstrating and confuting the opinion entertained by certain theorists that the removal of a live branch will prove fatal to all the correspondiug roots supporting it.

I have repeatedly fallen in with pine-root stools which continued their vitality for many years after the tree was wholly cut down, with the face of the stool healing over from the outside as regularly round the whole stool in the self same way as a wound on the trunk of a tree after a branch was pruned off. In all such cases, it is found that the stools had, prior to the trees being cut down, roots united or naturally engrafted upon roots of an adjoining tree of the same kind, which roots continued to draw sufficient nourishment from the standing tree for the support of the stool for years after its own tree was cut away.

About ten years ago I found a larch stool in Scone Wood about ninety years of age, the tree of which was cut about ten years previously. This stool was a solitary one, too far apart from any larch or any other fir tree to nourish it. Yet this stool was in life, and healing all round. I got men with tools, and laid its roots bare.

They were all far gone with decay, save one which was quite fresh. I traced it to its nurse, and found it to be lying across, and deeply embedded and strongly engrafted into, a healthy root of an adjoining ash tree. How is it then, that this engrafted root without the aid of a green leaf, nourished the whole stool, giving circulation to the sap all round, and producing the formation of sap-wood and bark? This is a question for botanists and theorists to solve.

I shall now make a few brief remarks on oak pruning.

Judicious pruning is a very important branch of forestry. I do not by any means hold that even judicious pruning will, as a whole, augment the bulk of timber in a tree; but, from my experience for nearly fifty years watching the results of the beneficial effects of trees for that period under my management, I certainly hold that early pruning, when followed skilfully up periodically, will have the effect of producing ultimately a much larger yield of clean, straight, valuable timber per acre, than would have been the case were the trees to remain in the unpruned state. No doubt there are individual trees that grow on certain soils naturally tall and straight in the bole, and therefore such trees require but slight artificial training, but, generally speaking, with few exceptions all oak trees require skilful training, and when trees are properly treated in this manner, a large number can be reared per acre, which are not so likely to be blown over with high gales, or have their limbs torn off.

I should fancy that opponents of pruning never themselves had the experience of seeing the beneficial results of systematic pruning. The benefit accruing from such training is not to be obtained in a few years. An arboriculturist treating a young plantation in this way, and following up its training, may take forty or fifty years before he can see the actual result of his operations.

Of oaks that were pruned at Scone under my directions some forty-five years ago, hundreds of them are at present in the way of being cut up at the saw-mill for the building of railway waggons, and to me it is most satisfactory to find the timber so sound, free from blemishes, and beautiful. I have seen pruning performed so barbarously, mutilating trees in such a manner that it must have proved disastrous in the highest degree ruining the constitution of the trees, retarding their growth, and ultimately yielding faulty timber. Such pruning should not upon any account be tolerated; and when such timber comes into the hands of tradesmen it is no wonder that pruning is condemned. But the effect of judicious pruning is of an opposite character. Young oak trees from the nursery for planting into the forest should receive no further pruning than the shortening of contending shoots, or any individual strong side branch. When they arrive at six or seven feet in height, they should receive a regular course of training by pruning, when most of the work can be performed by the use of the pruning knife. The pruner should always begin at the top of the tree, shortening rival shoots with the leader, more than half their length. Strong rambling side branches should also be shortened fully one-half; and when a tree is found over-studded with strong branches lower down the stem, some of these ought to be thinned out and pruned from the stem. Young trees at this stage of growth should be so well balanced and shaped, that little or no pruning will be required for several years after. In the next course of pruning, the pruner ought to be provided with ladder, pruning-saw, pruning-knife, and shears on handles about seven feet long.

Before ascending the tree, the pruner should examine the tree minutely, and see the operation that will be required to balance and shape it properly. After ascending he should begin at the top, shortening the rival leader, if there be one, but as there is often a difficulty in reaching a rival top shoot, the pruning shears will require to be brought into requisition to shorten it.

The pruner, in descending the tree, should shorten extra strong branches at least half-way in. These should always be cut over, at a lateral small branch, or twig, of an upright growth. Strong branches growing pretty low on the bole should be shortened well in near the bole, in order to throw vigour up the stem of the tree. At this course of pruning a few branches ought to be pruned away at bottom, close to the stem.

Other successive courses of pruning should be conducted on the same system, with this addition, that more branches will be required to be pruned close from the bole.

The point to be studied for the safe guidance of the pruner is—What is the largest size of a branch that can be pruned from the bole without leaving any blemish in the timber? The health and vigour of the tree is the safe guide for this operation. I have seen the boles of trees thirty-five to forty years of age after being pruned healing at the rate of half-an-inch from each side of the wound, being an inch in the year, whereas trees in a less vigorous state did not heal over one-fourth of an inch in a year.

Therefore the health and vigour of the tree should be the guide, so as not to prune a branch from the bole of a tree, if the timber of the wound will in any way etiriorate before it heals over. Rotten branches on the

holes of trees should be pruned off before they are affected with rot at the base, in order that the wounds shall heal before decay takes place. Great care should always be taken against over-pruning, as thereby trees are retarded in their development, and rendered very unsightly. Trees at the last and final course of pruning ought to be left with their heads varying from one-half to one-third of the height of the tree. Oak coppice has become so utterly worthless that pruning may in the meantime be discarded.

Mr. J. McLaren, Hopetoun, said he was very much in favour of judicious pruning. He was sorry to see so little of it carried on in the country. As to the branches taken off killing the roots, he did not believe in that at all. If our trees were well pruned and well balanced there would not be so many blown down in our policies and plantations. (Hear, hear, and applause.)

Mr. McGregor, Ladywell, corroborated all that had been said regarding the benefit of judicious pruning. He advised young foresters to read Lindley's "Theory of Practical Horticulture" on this subject. With regard to the question of the pruning of branches causing the death of roots, he would like to ask the converse question, "If the roots are cut would the branches die?" Now if he had to prepare oak trees for transplanting, his first operation was to cut all the roots, and yet he did not discover any of the branches died. (Laughter.)

Mr. Dunn, said that arguing from the theory put forward, a cutting of the stem or branch of a tree would die; yet, on the contrary, such cuttings very soon formed roots and grew vigorously. (Laughter and applause.) And again, if cuttings were made of the roots of certain trees they would quickly produce stems. (Hear, hear.) It was, he thought, needless to discuss that point further in reference to pruning. He thoroughly agreed with Mr. McGregor that young foresters ought to read Lindley's "Theory and Practice of Horticulture," for it bore quite as much on arboriculture as on horticulture. In regard to pruning, he maintained that the more judiciously it was practised the better it would be for the arboriculture of the country. There is a great difference between judicious pruning, and mutilation or the cutting off of big limbs. Many a fine and beautiful tree had certainly been ruined from the injudicious use of the pruning saw. They should go round the trees when they are young and tender; for them as much could be done in one day as could be done in a week, when the trees had got up a bit. His motto would be "Prune when small, or not at all."

Mr. McCorquodale quite agreed as to pruning young, if a forester got charge of a young plantation. But when a forester went to a forest in all stages of growth and which had been neglected, he must use the saw. Then he should go up the large trees with a ladder and shorten the straggling branches half-way, to prevent them being broken and destroyed.

Mr. Dunn said that when things got into such a state, it was right to apply the saw to put them straight; but then that was a state of neglected forestry, and would never occur in well managed woods.

The President said he was not aware of any case that had been noted, as the ingrafting of two such different plants as a pine and an ash, as mentioned by Mr. McCorquodale. The case was a very interesting one. As to pruning—everything turned on whether it was done judiciously. Every green leaf that was taken off diminished the supply of organic matter to the tree. The main question was the proper balancing of a tree, and of its being pruned so as to form a stem suitable for timber purposes. Probably if the only use of trees was to produce fire-wood, the best way would be to allow them to grow without pruning or training. But for timber purposes pruning was best.

Mr. Gordon, Luss, said he knew of instances of the growth of wood on larch, and Scots pine roots or stools, which were, of course, without leaves, and which were near no other trees.

The President said there must have been a sufficient store of organic matter in the roots to provide for a certain amount of growth of wood and bark for a short time, but that time would be limited where there were no leaves and where there was no natural root grafting.

—*Journal of Forestry.*

DIFFERENT MANURES IN POTATO CULTURE

An article in *The Field* last year, relating the results of an important series of experiments on the use of various manures in the cultivation of potatoes, conducted in 1881 at the Munster Agricultural and Dairy School, near Cork, attracted a good deal of interest throughout England. During the past year a similar series of experiments were conducted at the Albert Model Farm, Glasnevin, near Dublin, and the results obtained ought to be made widely known. The experiments were carried out under the superintendence of Dr. C. A. Cameron, Dublin, well known as an able and experienced agricultural chemist.

The manures tested were kainit, nitrate of sodium, sulphate of ammonia, and mineral superphosphate, and they were tried singly and in various combinations. The results obtained will be most clearly shown by the following table, in which the plots are arranged in order of the highest marketable yield:

Manure.	Cwt. per acre.	Cost. £ s. d	Marketable potatoes. T. C. Q.	Small potatoes. T. C. Q.	Diseased potatoes. T. C. Q.	Total per acre. T. C. Q.
Nitrate of sodium ...	2	2 8 0	... 2 11 0	... 1 7 2	... 0 6 2	... 4 5 0
Mineral superphosphate ...	4					
Kainit	6	0 14 6	... 2 6 2	... 2 0 0½	... 0 6 2	... 4 13 0½
Kainit	2	1 11 6	... 1 19 —	... 1 12 0	... 0 2 2	... 3 14 0
Nitrate of odium... ...	1					
Sulphate of ammonia ...	1					
Mineral superphosphate ...	2					
Kainit	4	1 7 0	... 1 10 0	... 1 14 0	... 0 8 2	... 4 1 2
Mineral superphosphate ...	4					
Superphosphate	8	1 12 0	... 1 5 2	... 1 19 0	... 0 1 0	... 2 10 2½
Sulphate of ammonia... ...	2	3 0 0	... 0 19 2	... 2 2 2	... 0 5 2	... 3 7 0
Superphosphate	4					
Sulphate of ammonia... ...	3	3 6 0	... 0 8 2	... 1 18 0	... —	... 2 6 2
Kainit	3					
Nitrate of sodium	1	1 16 3	... 0 8 0	... 2 11 0	... —	... 2 19 0
Superphosphate	3					
Kainit	3					
Sulphate of ammonia... ...	1	2 3 0	... 0 8 0	... 2 3 0	... 0 0 1	... 2 11 1
Superphosphate	3					
Nitrate of sodium	3	3 8 0	... 0 6 2	... 2 3 0	... 0 0 1	... 2 9 1
No manure	—		... 1 3 3	... 1 9 2	... 0 4 2	... 2 17 0

This table is calculated to teach important lessons. The most striking feature in the Irish potato experiments in 1881 was the remarkable results brought out by the use of kainit. This year again kainit stands pre-eminent. It produced by itself the highest gross yield, and that, too, at by far the lowest cost. Kainit, applied at a cost of only 14s. 6d. per acre, gave a yield higher in gross weight, and only 4½ cwt. less in marketable tubers, than a mixture of nitrate of soda and superphosphate, costing £1. 13s. 6d. per acre. The marketable potatoes from kainit thus cost barely 1d. per cwt. for manure, while those from nitrate of soda and superphosphate cost nearly 1s. per cwt.—an advantage to the kainit of more than 13s per ton. Kainit in use with other manures also did well, generally adding to the yield. It will be seen that a mixture of kainit and superphosphate, costing £1. 7s. per acre, gave a much higher yield than a dressing of superphosphate alone, costing £1 12s. per acre.

The table indicates that superphosphate as a single manure ranks next to kainit, and there is no doubt that, judiciously applied, it forms a very useful manure for

potatoes. In conjunction with nitrate of soda, superphosphate gave the highest yield of marketable tubers, but with sulphate of ammonia it did badly.

Next to the pre-eminence given to kainit, perhaps the most important feature brought out is the very poor results realised by the nitrogenous manures, nitrate of soda and sulphate of ammonia. By themselves it will be seen that they gave very small yields—indeed, much below the plot that received no manure at all—in potatoes of a marketable quality. When given along with inorganic manures they did no better, having evidently, to some extent, neutralised the good influence of those.

Dr. Cameron analysed the sound potatoes from each plot, and the percentage of dry matter varied somewhat. The plot dressed with nitrate of soda and superphosphate stand highest, with 28·60, and the others follow in this order: The plot dressed with kainit, nitrate of sodium, sulphate of ammonia and superphosphate, 28·12; the plot dressed with sulphate of ammonia, alone, 28·12; that with kainit, sulphate of ammonia, and superphosphate 27·50; that with superphosphate alone, 27·04; that with nitrate of soda alone, 27·00; that with kainit and superphosphate, 27·00, no manure, 26·90; sulphate af ammonia and superphosphate, 26·10; kainit alone, 25·80; and kainit, nitrate of soda, and superphosphate, 24·30.

The column showing the quantity of diseased tubers does not bring out very startling results. It is curious to note that the nitrogenous manures produced little or no disease, while kainit shows about 7 per cent. of disease—a circumstance contrary to previous experience.—*Field.*

COST OF HILL PLANTING IN SCOTLAND.

The season for planting is now approaching, and while planters are busy making arrangements for having the work done, the question, What will it cost? will no doubt often be asked, and the answers will vary, not only according to the situation and nature of the ground to be planted but also according to the methods that each planter may purpose to adopt. As a few ascertained facts are of more value than any number of theories, the following statements, which have been received from one of the most extensive and successful planters in Aberdeenshire may be interesting to the readers of the *Journal of Forestry.*

"It is now about forty years since I began to plant and with the exception of the year 1846, I have planted every season more or less since then. During that time I have contracted for, and had the charge of planting about nine thousand acres, principally in Aberdeenshire and all this has been done with the 'hand-iron.'* The number of plants used has been from 3,000 to 3,500 per acre, so that that extent of ground has required about thirty million of plants, the sixth part of which, or five million, have been planted with my own hand. During the first twenty years the plants used were all two-year-old seedlings, and the cost of planting, *including plants and carriage of plants*, was from twelve to fourteen shillings per acre. The lowest rate at which I ever planted was ten shillings per acre; and that was for about two hundred acres on the hill of H—— in the parish of L——. This plantation, which is now in a very thriving state, was planted with two-year seedlings and required no upmaking. The hill of B—— in the parish of O. M——, containing 133 acres, was planted with two-year seedlings Scots Fir and Larch for 13s. per acre; the whole of the planting being done by four men and myself in *three weeks and three days.* This is now a healthy and valuable plantation.

"During the last twenty years I have used a good many transplanted plants *i. e.* two-year seedlings, one-year transplanted Scots Fir—especially where herbage was rank; consequently, owing to the increased cost of plants, and the rise in workmen's wages, the contract price of planting has gradually risen, and has ranged from 20s. to 30s. per acre, and in a few cases such as at R—— W—— in the parish of A—— planted in 1876-77, the price has been, owing to the size of plants and quality of the ground, as high as 42s. per acre. Between 1865 and 1870 the Hill of C—— containing 450 acres was planted with two-thirds Scots Fir and one-third Larch for 22s. 6d. per acre; and in 1871-72 the hill of M—— in the parish of R—— was planted for 25s. per acre. The extensive plantations on the estate of C. F—— were done for about the same price, while those on the estate of G. M——in Aberdeenshire and on the estate of T—— in Kincardineshire have ranged from 25s. to 30s.—the latter price having been got for planting ground that had previously grown a crop of Scots Fir, and where there was a risk of damage being done by ground game. In most cases I have undertaken to make good all failures that occur during the first three years, except such as are caused by ground game, fire, or the inroads of cattle and sheep."

These statements may seem startling to many of your readers, but they are not singular, as in "Grigor's Arboriculture," pages 56 and 58, examples of contract planting are given at 10s. and 10s. 6d. per Scotch acre, in the year 1830, while at page 62 other examples are given at 16s. and 19s. per acre, and it is importannt to note that the same system is still practised in the north, though at advanced rates. Of course it must be understood that this mode of planting is only suited for hill ground, where the heather is short and the soil free and open. The person whose experience I have quoted above, states "the greatest difficulties that I have had to contend with are where the ground has a close grassy surface." It must also be understood that the prices given above are only for plants and planting, and to this must be added the cost of enclosing and drainage where necessary. Still, with these items added the cost of planting ordinary hill ground will not exceed from 30s. to 40s. per acre, or say 500 acres planted and enclosed for less than £1,000. Surely that ought to be an inducement to proprietors in the north of Scotland to plant suitable portions of their hill ground.—Bon-accord.—*Journal of Forestry.*

* For a description of the "hand-iron" see "Grigor's Arboriculture," p. 54.

Trees to India by Mail.—A Western nurseryman writes us, that few people are aware how far young trees can be sent by mail with safety. Young seedling Evergreens are sent to England and the Continent, and deciduous trees much further. A package of young trees, of *Catalpa speciosa*, packed nearly dry, was sent to India with directions to bury the trees for 10 days after their arrival. The Conservator of Forests wrote that the trees opened, perfectly fresh, but he buried them for five days, and planted them; they all grew finely.—*American Agriculturist.*

Wood Better Than Iron.—Though it may appear peculiar a Philadelphia paper states that it is a matter of fact that many New England builders contend that the wood joists, encased in plaster, are proof against any ordinary fire, and for many reasons are much preferred by them to the ordinary regulation fireproof iron joists. The joists are "stripped" on the outside, and over these strips irons are run, and on these the plaster is spread. The theory is that in an ordinary fire these joists thus treated will be fireproof, and only when the fire has reached such a fury that the building must go any way will they be affected. Here comes in one of the advantages claimed for them. When a building is being burned by a furious fire the iron joists expand and crush out the walls and do other damage. The wood joists would simply be burned up without injuring the walls at all.—*Journal of Forestry.*

Peeling Bark by Heat.—Dr. Hough says that the inconvenience of crowding the work of peeling oak bark into a busy season of the year has led to the introduction of a process in Europe by the aid of which this work can be done at all seasons of the year. The apparatus consists of several large iron receivers of thin plate iron, strong enough to bear a moderate strain, and air-tight. The wood is placed in these, and steam at about 338 degrees Fahrenheit is admitted from a boiler so placed as to serve several of these receivers. They hold about half a cord each, and the time required varies from an hour and a half to two hours and a half, according to the season when the wood is cut. It is then taken out and peeled. If the heat is continued too long the bark again becomes adherent. One great advantage to be gained by this process in the working of coppice-wood is that it is not necessary to cut the wood at the season when the greatest injury is done to the stumps that are to send up a new growth. Careful experiments have been made by order of the French and Prussian governments upon the quality of the bark thus peeled, with favourable results.—*Chicago Lumberman.*

CINCHONA IN NEW AND OLD DISTRICTS IN CEYLON.—Our recently shaved Cinchona would be none the worse for rain, and we now pay more heed to its wants than to those of our much and deeply-regretted coffee. Our growth of cinchona is slow, but more certain than in new land. I heard of a field the other day, where Rs. 5 were offered for every plant to be found alive on a hundred acres! A Fact! This in many places has been a most disastrous planting year, especially in the new districts. From these old districts we have not shipped much as yet, but any one coming up here, if he takes a round-about journey through Hantane, Lower Hewahette and Puselawa, will be surprised at the quantity of cinchona now becoming visible. The trees are really one or two years older than they seem; but better stunted and slow progress, than mushroom growth and sudden death.—*Cor.* "Ceylon Times"

THE AMERICAN SUGAR TRADE.—It is stated in a recent report on the sugar trade of the United States, that the manufacture and consumption of glucose and Grape sugar has of late grown to an enormous extent. The present production is estimated at not less than 10,000 tons a day. While the product is chiefly used by brewers, it is also largely used as a substitute for sugar in the manufacture of confectionary and mixing of syrups. "New process" sugar, also, for which there is an increasing demand, contains about 20 per cent of glucose, and it is difficult to distinguish it from the pure product of the cane, for which it is no doubt largely sold. A low grade of sugar is also being extensively manufactured by the reboiling of foreign molasses. Philadelphia is said to do the largest business in this respect, to the extent of 20,457 tons, after which comes New York with 14,500 tons. This branch of industry is, however, not on the increase. The attempts to produce raw sugar from Beet-root and Sorghum do not meet with much success. Maple sugar is still, however, produced in considerable quantities in Vermont and some of the Western States, the annual production being estimated at about 10,000 tons. The total yield of Louisiana sugar for 1880-81—the largest since the Civil War—was over 120,000 tons.—*Gardeners' Chronicle.*

THE ACTION OF MANURES ON FRUITS.—Cultivated plants are the inheritors of whatever benefits or disadvantages they may have derived from their predecessors. The thing is obvious enough to those who look on plants from an evolutionist's point of view; and the practical outcome is that, except under special circumstances, or for some special purpose, it is best, in our attempts to improve upon that we have got, to deal with a plant that has been in cultivation for a long time, and so avail ourselves of its stored-up inheritance. It would be a long uphill work to start afresh with the Crab or wild Pear, for instance, although for the sake of getting a new "break" or more robustness of constitution it may be desirable sometimes to begin again at the beginning, or at least to infuse some less conventionalised blood into our plants, if we may so speak. A curious illustration of the contrast between the wild and the civilised condition is afforded in Professor Goessman's paper on "Mineral Constituents in Plant Growth" in the *Transactions of the Massachussetts Horticultural Society.* The Professor has been experimenting on the difference in chemical composition between Vines unmanured and Vines manured. In the course of his experiments he analysed the juice of a wild Vine (Vitis Labrusca) grown without manure, and the juice of the same Vine when treated with manure. At one bound the sugar rose from 8·22 per cent. in the wilding without manure, to 13·67 per cent. in the same wilding appropriately fed. This shows the advantage of the manure. But now, looking to the analysis of the cultivated variety (Concord), we find that in its juice, even when unmanured, the sugar amounted to 13·89 per cent., so that the cultivated variety, without manure at all, yielded a larger percentage of sugar than did the wild form with ample manure. The increase of sugar is coincident with a large increase of potash, and a largely diminished proportion of lime. In the case of Strawberries the wild unmanured variety contains much less potash, much more lime, much less magnesia, much more iron, and about the same percentage of phosphoric acid as the cultivated and manured variety. The wild Strawberry, moreover, contains one part of acid to two of sugar, while in the cultivated varieties the proportion of acid is one to four or more of sugar.—*Ibid.*

PLANTING VINES.—I lifted a very old Vine the other day which had never done well, and found the main roots all curled up into a mass. The roots when planted had not been properly spread out, and consequent had never left the ball—a fact which should be remembered by others when planting Vines or anything else that has been grown in pots.—*W. Ramshaw, Gr. Perry-stone, Ross.—Gardeners' Chronicle.*

VINES: INDIRECT EVIDENCE.—The fact that the American Vines resist or do not succumb to the Phylloxera is being acted on in a large scale in France, the American Vines beingused as stocks whereon to graft the better Vines of France. At first there was some doubt as to the real efficacy of the process for practical purposes, but that doubt is now settled, and, as if to prove it, thefts of American Vines from nurseries have become frequent. Thus, near Montpellier one night 850 plants were stolen and from another nursery a number of cuttings, valued at £200. The variety most affected by the marauders is one named Othello.—*Gardeners' Chronicle.*

VEGETABLE PESTS.—As an instance of the rapidity and thoroughness in which several of the Cactaceæ naturalise themselves in many countries, the following clipping from a leading daily affords striking evidence:—"A Bill has been introduced into the New South Wales Legislative Assembly for the purpose of empowering the Government to devote a certain sum to the eradication of the wild Cactus plant, popularly known as the 'Prickly Pear.' So rapid has been the spread of this vegetable pest that whereas, according to the statement of one member, £50 would have sufficed thirty years ago to rid the colony of it, a million sterling will, before many years, be required for such a purpose. It was stated that one proprietor of land in the colony had spent £1000 on his property in trying to destroy this mischievously prolific plant, but had not yet succeeded."—*Gardeners' Chronicle.*

THE PHYLLOXERA IN SOUTH-WEST FRANCE.—The *Vigne Américaine* gives the following statistics for the Department of Hérault, which may suffice to give our readers some notion of the extent of the disaster in one Department only. The number of hectares destroyed annually (a hectare = rather less than 2½ acres) was as follows:—In 1880, 19,000; in 1881, 20,427; in 1882, 26,267. The number of hectares treated by submersion during the same years was respectively, 1588, 1626, and 2283. The number of hectares treated by carbon sulphide for the same period was 1875, 4632, and 3541 respectively. The number of hectares treated by sulfo-carbonate of potash was 868, 1578, and 751 for the years before mentioned. The number of American Vines used as stocks whereon to engraft the finer Vines has increased from 2624 in 1880 to 10,918 in 1882 in the Department in question.—*Gardeners' Chronicle.*

CINCHONA: HYBRID VARIETY.—A good deal ofattention has been attracted in India and Ceylon to a Cinchona, which there is little doubt is a hybrid between C. officinalis and C. succirubra. I shall have occasion to deal more in detail with it in a succeeding report. Dr. King reports from Darjeeling, May 28, 1881:—"Mr. Wood's analysis showed that this variety yields a bark rich in quinine, and steady efforts have been made to increase it. During the year 85,000 plants of this hybrid were put out at Mungpoo, and 5000 at Sittong, bringing up the full number now on the plantation to close on 200,000." Dr. King further writes to me, October 8:—"Next to Ledgeriana our most promising bark is what we call our 'hybrid.' The first plants of this hybrid appeared amongst some seedlings raised from Ceylon grown seed sent to us by Dr. Thwaites. The plants look as if they were a hybrid between succirubra and officinalis. In habit of growth it resembles the former, but the leaves differ, and at a distance a patch of it looks more like officinalis than succirubra, having the dull heavy green colour of the former. Chemically the bark resembles that of officinalis. With us this hybrid offers to do splendidly at an elevation where succirubra won't grow well. Officinalis never has thriven here. I believe our plant to be a hybrid, because it never comes true to seed. Seedlings come out nearly pure officinalis."—*Kew Report for* 1881.—*Gardeners' Chronicle.*

CINCHONA CULTIVATION IN JAVA.

The Mutual Influence of Stock and Scion in the case of grafted Trees.

The reports of the able and keenly observant cientist who is at the head of the Government cinchona enterprize in Java are always interesting, but that for the closing quarter of 1882, a translation of which we give today, contains facts and suggests inferences of more than usual importance. It will be observed that in "planting out," Mr. Moens, while giving, as is natural, the preference to Ledgerianas, does not neglect the stout-growing succirubra or even the slender officinalis. It was the thin-stemmed habit of this species as well as the difficulty of growing it in West Java—the "Preanger Regency" (where all the Government plantations are situated)—which led to a strong prejudice against it on the part of private planters, and we came away with the belief that this prejudice was insuperable. But besides the fact recorded by Mr. Moens of the abundance of quinine in the root-bark of *C. officinalis*, the result of an official visit to Mid-Java by this gentleman has brought to light the hitherto unsuspected existence of soil and climate, so specially suited for this species, that a plantation only four years old shews growth and vegetation beyond what Dodabetta can display. As the altitude of the Java plantation is only 4,000 to 4,500 against between 6,000 and 8,000 on the Nilgiris, we can well imagine superior vegetation. As the soil and climate which suit *C. officinalis* well are sure also to be favourable to *C. Ledgeriana*, we may now anticipate a considerable spread of culture of the latter in Middle Java. Whatever may be the other merits of *C. officinalis*, it does not seem to be suited to supply stocks for the grafting of Ledgerianas. The want of affinity is such that success has not been obtained in a single instance. We are now very curious to learn, on reliable data, whether this absence of affinity extends to the refusal of the two kinds to hybridize? It is at least curious that while Mr. Moens mentions hybrids between succirubra and Ledgeriana he says nothing of hybrids between the two superior kinds. Can it be that there is a closer relationship between the robust-stemmed and large-leaved succirubra and the kingly Ledgeriana, than between the latter and the crown bark trees? It looks like it, for not only do grafts of Ledgeriana succeed exclusively on red bark stocks, but now Mr. Moens is startled himself while he startles us by facts obtained in analyses which seem to shew that stock and graft mutually influence each other, so as to modify the quality of the bark of each! Now, apart from the almost universal opinion of horticulturists, that there is no transfusion of quality from stock to graft, or *vice versa*, there was Mr. Moens' own experience of the first succirubra tree on which he tried the process of grafting Ledgeriana. The graft in that case preserved perfectly intact, and uncorrupted by the feeding juices derived from the red bark stock, its inherent quality of a bark rich in quinine. It was this fact and the fear of deterioration from hybridizing that led Mr. Moens so largely to extend the experiment of grafting his best Ledgerianas on to red bark stocks. Pursuing the process under double glass, Mr. Moens was largely successful, but now that his plantations of grafted plants are four years old, he is troubled by the results of analyses of barks of graft and stock, which seem to prove that while the bark of the supporting plant is rendered abnormally rich in quinine by its junction with the Ledgeriana graft the bark of the latter is deteriorated by the influence of the stock into a yielder of cinchonidine and cinchonine! As the stock bears but the smallest proportion to the tree growing on it, of course the improvement in the bark of the stock plant as a quinine yielder is no compensation for the deterioration of the Ledgeriana bark. If further experience confirms the extraordinary and unexpected results now obtained, the inference to be drawn seems to be that it would be well to direct attention to experiments in grafting pieces of Ledgeriana trees on to succirubras, in order to improve the bark of the vigorous growing trees. Mr. Moens' experiments with open-air grafting, especially in the case of more mature stocks, have not, however, been encouraging. We should like to hear Mr. Wm. Smith and others on their further experience in this direction. Our strong inclination is to believe that as Mr. Moens' grafted trees progress in age the Ledgerianas will assert and preserve their superiority. The twigs pruned away, even now, are mentioned as yielding very valuable results. But Mr. Moens, like a true and honest man of science, records facts as he obtains them, no matter whether they accord with or go counter to theories formed by himself or others. Years ago we rather shocked our good friend Mr. Gammie by saying: "Let us have seed from Ledgeriana trees and we'll take our chance of sporting and even of hybridizing." Mr. Gammie came subsequently to admit that we pretty well hit the mark, and now here is Mr. Moens admitting that the difference in bark of carefully selected and indiscriminately gathered seed of Ledgerianas is only 25 per cent in favour of the selected: the latter yields 12 per cent of quinine, while the unselected but unhybridized yields 9: averages in both cases. Now, considering the delay and expense which are saved, is it not preferable to propagate from unselected seed? Poor and sickly-looking plants can always be rejected, and, with close planting, those which give the worst results on analysis of bark can be gradually uprooted. But what if the once much-dreaded hybridization occurs? Just what has occurred in Ceylon by the intermixture of succirubra and officinalis; the production of trees which by their vigorous growth and robust habit make up for a lessened percentage of valuable alkaloids in the bark. Mr. Moens thinks well of the succirubra-Ledgeriana hybrids if only the seeds will come true to type. There is reason to believe they will—that the hybrids are not transitory productions but permanent types; and, if not, then we must resort to propagation by cuttings. Clearly those who have soil and climate suitable for Ledgerianas will do wisely in getting as much seed as they can from trees, the barks of which analyze from 7 to 12 per cent quinine, and from their nurseries to plant out closely all save puny or sickly plants. An *average* of 9 per cent quinine would pay amply. But, hold! Mr. Moens' experience is that, if you shave Ledgeriana trees, the natural bark of which gives, say, 9 per cent of quinine, the renewed bark at one year old will give only 7 per cent, and that it is only when left on the tree to the third year that the renewed bark recovers its normal position as a quinine bearer. This, if a universal result, which remains to be proved, is disappointing; but, if, by shaving each year, a renewed bark containing 7 per cent can be obtained, the wise thing will be to gather the bark year by year, rather than wait three years for 9 per cent or four years for 12 per cent. Of course, further reports may modify conclusions, but we very decidedly feel, at present, that cinchona planters who have soil and climate suited for Ledgerianas would act wisely in propagating and planting largely from seed as pure as can be obtained. And,

should hybrids appear in their nursery beds, we have no doubt they can sell them to advantage to planters not so favoured as regards soil and climate. For hybrids between succirubra and Ledgeriana, as well as those between succirubra and officinalis, there seems a great future in the higher altitudes, colder climates, and stiffer soils of our mountain regions.

From the table of analyses attached to Mr. Moens' valuable report, it will be seen that the barks of true Ledgerianas gave from 5·94 per cent of quinine up to 12·37, and from 7·51 to 13·61 of total alkaloids. The constituents in the latter case were :—

Quinine	12·37
Cinchonine and amorph. alk. ...	1·24
Total...	13·61

Then from broad-leaved succirubra-like trees and their descendants, such results were obtained as from 2·08 to 11·10 of quinine. In one case the constituents were :—

Quinine	10·33
Cinchonine and amorph. alk. ...	2·75
Total...	13·08

The tree, probably a hybrid, which gave only 2·08 of quinine gave altogether

Quinine	2·08
Cinchonidine	3·77
Cinchonine, &c. ...	2·32
Total...	8·17

Even that would not be an unprofitable tree to grow, as the renewed bark would probably shew an improved percentage of quinine. But we need not add to Mr. Moens' analyses of the table further than to draw the attention of our readers to the curious composition of the bark of Ledgeriana grafted on succirubra :

Quinine	4·52
Cinchonidine	1·24
Cinchonine	0·79
Amorph. alkaloid ...	0·98
Total...	7·53

The graft in this case was from an unselected tree, and we suspect that with advancing age (the tree was only 4 years old) the bark will improve. In due time Mr. Moens will tell us what occurs, in addition to all the valuable information he has already supplied to the world regarding cinchona culture and the peculiarities of barks in their proportionate yield of the various alkaloids.

CINCHONA.

Report on the Government Cinchona Enterprize in Java for the 4th Quarter 1882.

(Translated for the "Ceylon Observer.")

The months of October and November were rainy: in October on several establishments the amount of rain measured was from 329 to 553 mm. spread over 26 to 29 days. December on the contrary was again abnormal and was among the driest months of 1882. Planting out could not in consequence be continued, and at the end of the year a great number of plants, intended to be put out, were left in the beds. During the quarter there were put out 67,000 Ledgeriana, 24,500succirubra, and 21,000 officinalis. The harvesting was continued to the end of December. The amount of bark then gathered was about 230,000 Amst. lb., of which 186,312 A. lb. was intended for sale in the Netherlands and 1,993 A. lb reserved for the local medical service. The dispatch was slow, on account of defective means of transport. On 11th October last another small parcel of succirubra bark was sold, belonging to the harvest of 1881, which was originally reserved for the medical service for the preparation of quinetum. When this was given up the bark was sent to the Netherlands to be sold there. The whole parcel, amounting to 2,371·5 kilograms, fetched a net sum of *f*5528·90, or *f*2·33 per kilogram. The prices varied from *f*4·40 for 1st quality to *f*1·50 for dust per kil. By this sale the total return of the harvest of 1881 was brought up to *f*218,441·75. The experiments with grafting in the open air were continued during the quarter. Of the 88 grafts placed on 30 young succirubra stems in May 10 grafts on 6 trees are now likely to grow. The young scions are growing vigorously and are now about two feet in length. On large succirubras grafting does not succeed. Ferule grafting, while it was performed on a large scale in the nursery boxes under double glass, was also tried outside, Of 44 grafts placed in this manner in June on 14 young trees eight are still lwing, six of which have already grown well. In September and November 69 more of these grafts were placed on 34 trees, hut not one of these has succeeded. Experiments with crown grafting all again failed as formerly. The results of the analyses performed during the year are, so far as they are of any special interest, appended hereto in tabular form. 1—24 are alkaloid determinations of four year old descendants of *C. Ledgeriana*, which exhibit the type of this variety and prove that propagation by seed does no harm to the yield of quinine, so long as the seed is pure and not hybridized. Analyses 7 and 16 are of bark cut from ten trees, which were not picked out but ,taken just as they stood on one of the terraces, so that they gave for the whole plantation the high average of about 9 per cent quinine, whilst picked trees of good type, even of that age, contained a as much as 12·29 quinine. The analyses 18—24, of bark of private plantations, show that the exceptional trees are not alone found in the Government gardens. The analyses 25—38 are all of bark cut from vigorously growing broad-leaved individuals, which have the appearance of being bastards, in which succirubra has had a share. The yield of quinine varies greatly, though it is sometimes very high, and should these plants, raised from seed, continue to preserve their type, the cultivation of them should be very profitable, ss they grow more easily and rapidly than *C. Ledgeriana*. This will he tested. Whilst the bark, renewed on Ledgeriana trees, which were shaved, after one and two years had not yot returned to its original yield of quinine, it now appears that a period of three years is sufficient for the purpose. The original bark of the trees of which the renewed bark is now gathered, containing 9·26 per cent quinine, contained in 1879 only 7·8 per cent quinine. The analyses 45—54 of specimens of the harvest, obtained from the pruning of the Ledgeriana gardens, shew how these young branch and twig barks already yield an excellent material for the manufacture of quinine. No. 5 was obtained, by pruning, from one to three year old trees in the gardens formed of grafts. The analyses 41—44, 55—57 and 59 relate to grafted trees. These investigations deserve to be continued, as both the high yield of cinchonine and cinchonidine by the Ledgeriana grafts and the high yield of quinine by the succirubra under-stems is curious, and would lead one to suppose an influence of the two upon each other if anal. 42 did not contradict this, so far as the Ledgeriana is concerned. The analyses 60—63 of officinalis confirm the belief that the root bark of this variety is usually rich in quinine; that at Lembang, although growing with great difficulty, it forms a good deal of alkaloid; and that the narrow-leaved form, in British India, named *C. angustifolia*, here also has a high yield of quinine. The analyses 66—67 of *C. cordifolia* give for this variety a notably higher yield of quinine than has hitherto been met with. During the quarter, in fulfilment of an order of the Government, the Director has caused a search to he made in the tracts of natural forest, where cinchonas intermingled with various kinds of trees, have been found. On the occasion of this journey it was found that the limate of central Ja va appears to be more favourable than cthat of west Java for *C. officinalis*. Thriving plantations of this variety are found, among other places, in the district of Wonosobo, at a height of 4,000—4,500 feet. They far exceed in growth the gardens of Dodabetta in the Nilgiris.

Bandong, J. C. Bernelot Moens,
10th Jan. 1883. *Dir. Govt. Cinchona Enterprize.*

Census of Plants.

Plants in the Nurseries.—Ledgeriana, 820,700 (including 3,750 cuttings and 13,000 grafts); succirubra, 198,300; officinalis, 186,800: total, 1,205,800.

Plants in the Open.—Ledgeriana, 694,900 (including 85,000 cuttings and grafts, and besides the more or less 6,000 original Ledgerianas); Calisaya and Hasskarliana, 445,500; succirubra and and caloptera, 474,500; officinalis, 475,500; lancifolia, 9,000: total, 2,099,400. Grand total, 3,305,200.

Review of the Alkaloid Analyses of Java Cinchona Bark Performed during 1882.

No. 42 scion of mother tree No. 89, sample of 21 trees 2 year bark. No 43 scion of unpicked trees, leaves red on the under side; bark of ten trees 2½ years old. No. 41 scion of unpicked trees, bark of 9 three year old trees. Nos. 45 to 54 harvest. The bark of young branches and twigs mixed. Nos. 55 to 57 stems on which the Ledgerianas, analyses 42-44, are grafted. No 58 harvest. No 59 stem on which the Ledgeriana, analysis 41, is grafted. No 60 bark of shoots from stumped trees. No 61 root bark of the stumps. No 63 very narrow leaved variety. No 64 renewed bark of the tree to which analysis 18 of 1881 refers. Nos. 65 to 66 stem bark of ten year old trees. No. 66 do. No 67 branch bark of do.

ARECANUTS.

The following notes by a Ceylon planter are of interest at a time when Areca cultivation is engaging the attention of Europeans:—

Ceylon Varieties.—Three—besides a wild (indigenous?) variety, with a red blossom, viz. the common or Sinhalese, the Hamban, and the Rata Puwak! The fruit of the latter will not stand curing, but, used fresh, is preferred by the better classes amongst the natives, and commands a high price in consequence locally, but the demand would probably prove limited. There are still some doubts whether or not the Hamban Puwak, though it can be, and is, cured is sufficiently close-grained to keep long enough, or suitable for export; but if so it may be regarded as a superior variety, judging by the size of the nut. Both the above come into bearing earlier than the Sinhalese Puwak. The latter however is a heavier bearer; the nut very close-grained, and consequently keeps well when cured—representing the bulk at least of present exports. Nevertheless in competition with foreign varieties it commands the lowest price in the Bombay market!

Other Kinds.—The "Mysore"—worth considerably more than the Ceylon nut; and the "Shriwardhun," which is said to realize about twice as much as any other—or about three times the value of any exported from here at present! This is according to Simmonds' "Tropical Agriculture"—and confirmed by recent correspondence. It stands curing equally well, judging by samples of the *cured nut* received from Bombay. The former (Mysore) species is cultivated to some extent by the priests in parts of S. India; and is also used as a *shade tree* for cardamoms. The latter is grown at present only in a small native state called Shriwardhun.

There are a great many other varieties to be found in various parts of the east, but I am not aware that they are any of them worthy of special notice. Java has a very large kind, said to be identical with the Hamban Puwak.

Yield.—I have counted about 1,000 nuts on each of the Ceylon species; and good trees of the Sinhalese Puwak are said to give considerably more than this during the year. Under favorable conditions of soil and climate, 300 nuts annually is believed a safe average to calculate on.

The Hamban and Rata Puwaks come into bearing in the 4th to 5th year, a year or so earlier than Sinhalese." But this with all of them depends greatly on both *soil* and *climate*. In a very poor soil the plants makes but slow growth at first, but develop into good and fruitful trees eventually, possibly, equally with leguminous plants, possessing the power as they grow old of drawing nourishment largely from the atmosphere. Anyhow they have the merit of thriving amongst an undergrowth of weeds, so that but rough attention to the latter is a *necessity*—and I have strong doubts if clean weeding is beneficial to them! Both *tree* and *fruit* seem free from enemies of any kind, save man; and a property when once established—as pointed out by a sagacious headman—has the merit of making itself permanent; young trees from the nuts that have been allowed to drop continuously coming on to supply the place of those that have become worn out or unfruitful, and they should then be cut down. The trees continue to bear full crop till about the twentieth year (after which the sample is also apt to degenerate seriously), and the yield is usually very regular.

Statistics.—The trees admit of close planting—6' × 6' (or—as I should prefer them—12' x 3'; and perhaps better still, in *double-rowed* avenues of 21' × 3' × 3')—or say 1,200 trees per acre, not being at all too close. It takes on an average 12,000 cured nuts to one cwt. At 300 per tree, the

yield per acre (of 1,200 trees) per annum would thus be 30 cwts, and as far as can be made out this is not at all too high an average yield to calculate on. The local wholesale value at Galle or Colombo is usually about R8 per cwt.—or, at 30 cwt, R240 per acre, equal to a nett profit of say R140—as R100 may be considered a liberal expenditure. In Madras and Bombay about R15 per cwt. is generally realized for consignments from here: it may therefore pay better to ship. And of course if the more valuable kinds are grown the profits will be still further greatly enhanced—probably more than doubled. Uses, and perhaps a good market, may hereafter be found for the fibre? The industry not having as yet been put to the test on a large scale, I may be over-rating it, but don't think so; and it would at least be interesting to have the opinion of some of your native correspondents. If not, with *practically* an unlimited demand, *hundreds of millions* of people in China, India, &c., using arecanuts—it ranks second to few other enterprizes and offers at the same time a safe investment for limited capital. I have anyhow heard it put down as, as lasting and good an investment as "coffee in Haputale"—a compliment being meant both to the coffee there, and areca!

PLANTING IN BURMAH.

The Rangoon correspondent of the *Indian Agriculturist* writes as follows:—"I see from correspondence in the Calcutta papers, that Tea planters in Assam are deploring the increaased production of Tea and the absence of new markets. What will they say when the hills in the province at Tavoy and Tounghoo are covered with the Tea plant? If labour were more plentiful, there would be plenty of room for Tea production in British Burmah; and the success of the Arakan plantation, and of a small one under Mr. Petley's management at Tounghoo, which also includes Coffee and Chinchona, shows that, even with the labour difficulty, success attends Tea down here. With the opening of the railway to Tounghoo, and the probable influx of Shan cultivators from beyond our frontier, no doubt Tea and Coffee gardens will be largely increased in Burmah in the course of a few years. Until that time, Tea manufacturers in India might do worse than get up a trade in dry and 'pickled' Tea with the Burmese. The latter description now nearly all comes from Mandalay, and the coarsest leaf does best for it. It is consumed in every Burmese house, and accompanies every invitation to the numerous ceremonies held annually or oftener in almost every Burmese family. When King Theebaw started his monopoly in 'pickled' Tea, a Burman trader introduced the article from some gardens in Chittagong, and obtained a fair profit from his enterprise. Assam could supply British Burmah with 'pickled' Tea as easily as Mandalay does, and possibly more cheaply. Why, again, should China Tea of the weekest kind be obtainable in small paper packets for an anna or two at every Burman village, when the smallest package of Indian Tea obtainable is a 1-lb. tin, at a cost of Rs. 1-4 or Rs. 1-8? If Indian manufacturers wished to open a trade with three millions of Tea-drinkers and Tea-*eaters* down here, they might easily do so. For the drinking portion of the public, a good Tea should be packed in cases—in small packets, and sent to the shops here for retail at small prices. The Tea would then get known amongst the Burmese, who do not care to invest in 1lb. of the article at one time. When it was generally known, it could not fail to be appreciated, from its superior strength and flavour, and it would in a year or so oust the inferior Chinese description, now largely imported from the Straits. But the Chinese have long ago appreciated the fact that to obtain large sales they must pack their Tea in small packets, which can be profitably sold for an anna or an anna and a half, whilst Indian manufacturers pack in such sizes as require an expenditure of about sixteen times that amount. For the manufacture of pickled Tea of the Burmese market, it would perhaps be necesary to get experienced hands from Upper Burmah, but the trade is a large and paying one, and this would eventually remunerate Indian Tea-gardens handsomely if they could secure it."—*Produce Markets' Review.*

THE BRAZIL COFFEE CROP

is thus discussed by the *Rio News*:—

The many reports now being received from various parts of the coffee districts about the large falling off in the coming coffee crop should be expected with several reservations. It will be remembered that last year both drouth and rain were brought forward as injuriously affecting the coffee crop, and yet Brazil easily produced one of her greatest crops. Admitting that drouth and rain have here and there caused more or less injury, especially to the old plantations, there still remains the important consideration that a great part of the present producing area is composed of young orchards, the majority of which have not yet reached their maximum of production. For many years to come the tendency will be toward increased production through all these new districts, and that in a greater ratio than the decrease from the decaying plantations and from the average effects of drouth and rain. There has long been a belief among planters that they could influence prices by concealing stocks and circulating discouraging reports about the crops. A greater mistake never was committed. Even were it true that such a policy will deceive consumers, it must be remembered that it deceives producers as well; hence both parties are left in the dark. A frank statement of the quantities produced and of the crop prospects can not be other than advantageous to both consumer, and producer, for, while it gives the one a correct basis upon which regulate prices, it gives the other an equally correct basis upon which to regulate production. Had Brazilian planters known just how rapidly production was increasing and stocks accumulating during the last ten years, it is inconceiveable that they would have gone on planting new orchards and increasing the area under production. Correct information can be no more useful to the consumer than to the producer, and it is highly desirable therefore that the policy thus far pursued should be abandoned. After so many years of these false reports, the planter ought to have learned that the merchant really gives very little credit to them, and bases his calculations upon averages instead. They know quite as well as the planter just how much of a drouth it will take to offset the natural increase in production, and just how much to cause a decrease. And they know perfectly well that there has not as yet been sufficient cause for either of these results. [On the other hand the utterly unremunerative prices for last crop must have left many estate owners without funds to carry on cultivation.—Ed.]

RAINFALL IN TYPICAL PLANTING DISTRICTS IN CEYLON BETWEEN DECEMBER AND APRIL FOR FIVE YEARS.

The return, as furnished by the Surveyor-General at our request, does not yield the data we expected to account for lessened crops, either in amount of rainfall or number of days over which rain was distributed. We should require to see, what Mr. Giles Walker shewed, diminished temperature or the reverse, force and persistence of wind, amount and continuance of cloud in the sky, degree of saturation of the atmosphere, and so forth, in order to determine the power

of the weather as a factor in diminished crops. The rainfall figures are neither so complete nor so suggestive as we expected. The amount of rainfall and its persistency or otherwise are, no doubt, important considerations, as much in tropic as in temperate agriculture, and our readers may be able to draw some conclusions from the table as it stands, but, apart from records of cloud, wind and temperature, we can scarcely do more now than say what we have repeatedly said, that abnormal weather has added to the evil effects of *hemileia vastatrix* and grub in enfeebling our trees and lowering crops. With more seasonable weather we might hope for less fungus, less grub and more crop.

COMPARATIVE TABLE OF RAINFALL.

March 5th, 1883.

J. STODDART,
Acting S. G.

EFFECTS OF SHELTER IN PREVENTING DISEASE IN BLUE GUMS.—We regret that a communication dated Nuwara Eliya, February 9th, should have been delayed. It runs thus:—"The following facts may throw some light on the question: 'What ails our blue gums?' I have three nurseries, one within the jungle and thereby sheltered: one partially sheltered, and the other exposed to the full force of the S. W. monsoon. The latter has very few sound plants, the partially sheltered has a good many diseased, and the one in the jungle scarcely any; not 1%. Though this would tend to prove the monsoon has to do with the disease, it does not tell us how; and one would also conclude that cinchonas and tea sheltered by the blue gums would or should not suffer so much as those more exposed."

RUBBER ADULTERATION.—A Paris correspondent of the *Engineer* says:—"You are probably not aware that indiarubber is now adulterated with finely-pulverised cork. Pulverised cork is worth about 4½d per lb., while the indiarubber to which it is added, "floating quality," is worth 9s. per lb. or more.—*Chemist and Druggist.*

TEA.—It is stated at Darjeeling that the tea season promises to commence early. New leaf is making its appearance in many gardens. With a little rain, manufacturing should commence in a few days. Coolies are suffering very much from fever on the Terai gardens, and labour is scarce in consequence. A few cases of small-pox have been reported from the Terai and Kurseong during the week.—*Pioneer.*

THE "MAN" TREE.—A correspondent asks:—"Can you tell me the English name of the timber the Sinhalese call 'man' or 'mann'?" "W. F." writes:—"There is no such name for a timber tree of Ceylon that I am aware of. In Moon's Cat. pf. 2, p. 28, No. 464, he gives the Sinhalese word 'Mān,' and 'Kiri. mān,' and 'Æt-kukuru-mān.' The former has no botanic name, the latter is the *Gardenia uliginosa* Rox., but is a small shrubby thorny plant. Send me a bit of the tree in flower or fruit. No English name for it."

MOCHA COFFEE.—In reputation this coffee has always undoubtedly stood high and is one of the choicest kinds grown in any part of the globe—in short, the palm for excellence in unroasted coffee may be said to lie between yellow Mocha (short or long berry), finest Blue Mountain (Jamaica,) and Cannon's East India plantation Mysore. Neilgherry Hill, Naidoobatum, and plantation Ceylon coffees may be classed next for weight and boldness of bean, and washed Rio, Costa Rica Guatemala, and other Central American sorts are also much liked by the home and export trade here for being of good colour and closely made; but none have ever gained the name that Mocha has, and singular to add, none have sunk into such obscurity as Mocha has in Europe for many years past. As far back as 1864-68, the year's imports, deliveries, and stocks of that description at this port were of small extent, viz:—

	1864 Tons	1865 Tons	1866 Tons	1867 Tons	1868 Tons
Imports	308	324	163	384	397
Deliveries, home consumption	534	216	109	211	252
,, export ,,	229	206	49	179	158
Stock, end of December ...	232	121	129	134	103

And only within the past three years the figures for the first forty-one weeks have also been very diminutive, as under:—

	Imports Tons	Home con. Tons	Exports Tons	Stock Tons
1882 ...	170	480	200	265
1881 ...	430	210	260	140
1880 ...	550	290	500	220

The above statement shows more clearly than any argument how insignificant a position Mocha coffee occupies as compared with other kinds, and also how undue an amount of interest has been directed to an article that has become almost entirely neglected and out of date in the United Kingdom. Mocha coffee is seldom or never drunk by itself, its scarcity and dearness here standing in the way of that, and it is principally used for blending with other grades that require greater strength and fulness of aroma and flavour. When skilfully mixed with fine East India plantation growths, it is pronounced by experts to be the perfection of coffee. From this scanty supply that comes in from abroad, it can easily be understood that the consumption of pure Mocha coffee by the general population is an impossiblity, without reckoning the almost prohibitory prices now ruling, which are, as they mostly have been in years gone by, much higher than those current for other descriptions.—*Grocer.*

Correspondence.

To the Editor of the Ceylon Observer.

VARIATION OF RAINFALL.

Waverley, Agrapatana, 10th Feb. 1883.

Dear Sir,—Your correspondent "From the Hills" in his letter of 7th instant says the excessive rainfall of last year, a record of which he sent you, was excessive in general over the planting districts, but as my rain-gauge does not corroborate this I send you my figures for the past two years, and as a check on last year's total my neighbour tells me he had 10 inches *less*, or say only 81 inches for 1882 :—

Rainfall at Portmore.

1881 total inches 89·88 January to December
1882 do do 91·33 do do

Inch 1·45 excess.

The elevation is 4,600 feet. For January 1883, I registered 3·59 inches.—I am yours faithfully,

ROB. C. BOWIE.

[Apologizing for the delay, we may say that the Agrapatana district seems to be climatically as well as geographically in Uva.—Ed.]

CINCHONA ON ST. HELENA.

February 22nd, 1883.

Dear Sir,—Has the writer of the paragraph beneath (quoted from a home paper) made a mistake, or do cinchonas grow at St. Helena?

In describing a visit to that island he says :—

"However, reminded by our guide that we had still three miles to walk to Longwood, we left the valley, and followed our track through *thickets of cinchona trees* where our attention was constantly occupied by flitting visions of some new bird, or the examination of flowers and ferns."

The italics are mine.—Yours faithfully,

NAPOLEON.

GUINEA GRASS, CATTLE AND CATTLE MANURE IN COFFEE CULTURE IN TIMES PAST.

Uva, 25th Feb. 1883.

Dear Sir,—According to promise I now send you a few remarks regarding my experiences in forking, manuring, &c., on coffee plantations. It was my fortune, about the year of the Indian mutiny, to become superintendent of a large property which needed to be manured. Uncle Sam informed me that my predecessor had recently planted some 13 acres of guinea grass, converting a piece of scrubby land into a guinea grass field, and that he had also purchased in Kandy or Matale 65 head of horned kine, and invited me to accompany him and inspect them and the field also. "This estate has," he said, "been second to none in the district, but the lower coffee must now be kept in heart with manure." The cattle were a motley lot, horned indeed they were, horns like Jack and the beanstalk, twiddling and twirling up to the skies—and the celebrated cow with the crumpled horn was there with horns so wide apart that a jockey might ride between them. Now I never could abide cattle with triumphant horns. "What do you think of them" said the Colombo agent? "Must sort them and keep only the best." "Umph!" he muttered, "gathered from the four corners of India I guess." What shapes and colours and ages they exhibited. I had to part with some 30 of them; and try how the guinea grass field would maintain the other 35. Besides the ravines were mostly planted with Mauritius grass to help out the fodder supply. For some half-a-dozen years, I managed to feed the "madu," and the increase was about equal to the decrease, and to manure *extensively* the lower part of the estate. The cattle shed was a small one, and it was very difficult to turn the manure in it. So I built a semicircular wall round half the shed and had the manure thrown into it and this acted in part as a turning for it. Then the rain from the side of the roof served also to decompose the straw and grass, so that when it was applied it might be termed "old rotten manure." Now I don't believe in what modern books tell us : that we are to apply "crude manure stuffs." We treated the coffee trees to ½ a basket of it, once in every two or there years, and it answered admirably, and in order to extend our operations had relays of coolies, one relay carrying the basket full of manure, say, past 30 trees or so, and the other putting down empty baskets and carrying the full ones past another 30 trees. It was in those days thrown into large square holes, say 10 or 12 inches deep, but now I cut holes in the shape of a horse-shoe and only say 9 or 10 inches deep. At the end of 6 years, I found the guinea grass field sadly failed and gave little grass, and had hard work to keep the cattle in good condition. Had it been in the lowcountry, I could have purchased fresh paddy straw at a reasonable rate and could have rented a paddy field and planted it with Mauritius grass—*a hint to all planters in the lowcountry!* And will it pay? Yes. During those six years it paid well, for, when we consider the transport of poonac to the hills, surely it pays to raise cattle manure, even if we have to apply bone dust also. Lately I have been forking in cattle per manure, but I prefer the old plan at any rate where the trees do not well cover the ground.

It would be difficult and unprofitable to apply fresh cattle pen manure : the quantity daily or weekly would be too small. Then cattle pen manure requires to be mixed well, or else it is all straw or dung. Finally, we can always regulate the dose per each tree and so avoid the stimulation of any kind either from nitrates or potash. I may mention I tried a paddy field near Galle and got it planted with Mauritius grass and for years and years it bore well. J. J.

IS COFFEE LEAF-DISEASE ON THE DECLINE?

Haputale, March 6th, 1883.

Dear Sir,—Can any of your scientific readers explain how it is that with two years of the most favourable weather for the development of leaf-disease Haputale should be so free of the pest? In this part of the district we have only had one slight attack during the above period—so slight that only one on the look-out for the enemy would have noticed Is leaf-disease on the decline?—Yours faithfully,

MORE LIGHT.

AN INSECTICIDE.

Dear Sirs,—I enclose particulars of an insecticide that I brought from England with me last month : it is an excellent remedy easily applied, and cheap. I have tried it on grasshoppers, ticks, crickets, &c., with satisfactory results. I have no doubt it would prove equally destructive to red spider.—Yours faithfully,

MOSQUITO.

[The substance referred to is the London Beetle Powder. It is claimed for it that the ravages of moths are effectually prevented, and bedrooms cleared of bugs in one night, beetles, bugs, crickets, cockroaches, flies and fleas, however numerous, are destroyed in a few nights by using the above. Harmless to domestic animals. An excellent insecticide for greenhouses." One of the testimonials runs thus :—"From the Rev. C. W. Grove, the Mythe House, Tewkesbury,

Gloucestershire, May 16th, 1877. Sir,—I think it only due to you to tell you that I have tried your *Universal Déstroyer*, and find it the most wonderful thing I have ever seen. My house and the hothouses and greenhouses were infested with crickets, woodlice, and other pests, and one application has very nearly freed me from them. I therefore wish you to make use of my name, if it will do you any service, as I should recommend any housekeeper or nurseryman to procure your insect powder without delay." The misfortune is that our cultivation is not confined to greenhouses, but spread over vast areas.—Ed.]

WHAT AILS OUR COFFEE TEEES? TRY FRESH SEED.

"A certain man had a fig tree planted in his vineyard; and he came and sought fruit thereon and found none. Then said he to the dresser of his vineyard: 'Behold these three years I come seeking fruit on this fig tree and find none: cut it down; why cumbereth it the ground?' And he answering said unto him: 'Lord, let it alone this year also till I shall dig about it, and dung it; and if it bear fruit, well; and if not after that thou shalt cut it down.'"

Dear Sirs,—The above parable applies very closely to the case of the coffee tree not only in Ceylon but in India. "W." has come forward with a long series of letters on a campaign showing that the world at large is wrong in drawing its conclusions as to the effect of leaf-disease. Such physiological amusements are all very well to one whose nature loves to wander afar into mysterious regions, but they do not help anyone to come nearer the truth. Up till lately I was always convinced that grave injury was caused to the trees, but I could not satisfy myself clearly. Now I will tell your readers what I know will interest them, and it will give heart of courage to those who have the framework of a coffee estate complete: that is, who have unexhausted land, good machinery and appliances, and labour abundant. I saw on one side of road on a wellknown estate in Munzerabad old weary-looking sapless coffee trees that well exemplified my text. They had been dug about and dunged with all the care and solicitude possible, and there these worthy old fellows stood still bearing a little, but looking terribly worn and dry. At a distance the amount of leaf deceived one just as in Ceylon—but, similarly, on close inspection, the wood was very saploss, and it was plain that the tree was unhealthy. Show this to a Ceylon planter and he would say:—"Put in cinchona, tea, cocoa, anything else—*the soil* is exhausted for coffee." Aye, so you might think. But, reader, turn this way just a yard off, merely separated by the road on which you are standing, and what meets your eye? Short, level, juicy, sappy, luxuriant coffee bushes such as pleased the planter ten years ago and *not since*. Before leaf-disease came, and *not since*. "Ah, but this is new land and highly manured," you say. "No," you are told. "This old piece of coffee was what people looked at formerly with pleasure, and this sheet of young coffee was an eyesore—a place that seemed to refuse to grow anything." This is the result of Coorg seed being introduced and persevered in. All over these properties I refer to, the Coorg seed is gradually superseding the played-out old coffee, and you are shown long sheets of beautiful dark luxuriant coffee flourishing in land that, in Ceylon, you would describe as "played out chena that might do for tea." Where is the wonderfully mysterious "wave of depression" that has swept over Ceylon? Not only have Ceylon men been blind to the danger of having but *one* product, but they also have refused to see the benefit of several varieties of coffee. In fact, they went so far as to be prejudiced against Liberian coffee, simply because it was coffee. But you will say—that is all very well to condemn Ceylon for not going in for this new coffee when you are not sure that the same benefits would result in Ceylon as have resulted in India. I ask in reply: "Has anyone given the thing an honest attempt?" Years ago one or two gentlemen in this neighbourhood turned their attention to trying the Coorg coffee. Someone asked: "Why don't you try the Coorg variety?" It was done. Those who began were laughed at, but others became convinced and joined in planting the new product, and results are beginning to appear. You know, I left Ceylon as great a disbeliever in coffee as you could find, but "facts are chiels that winna ding." Ceylon men may say: "What's the good of a product that gets leaf-disease? It will gradually go the same way as the other coffee has done." Well, I do not affirm that the new coffee will succeed in Ceylon, but, as it has had such a marked superiority over the old Munzerabad kind; as the old Ceylon kind may be equally inferior; and, as in the favoured district of Coorg the lucky planters calculate their crops by the ton and look down with benignant gaze on leaf-disease and its reported terrors; as such is the case, is it not worthy of a fair trial by those in Badulla, Matale and Dumbara and other similar districts whose soils *cannot* be worn out? They have the appliances for coffee, and surely the Colombo agents would vie with each other in presenting the successful grower of coffee with presents of manure, and offers to cure his crop free of charge. I was asked by the owner of a fine sheet of coffee (new kind): "If this were in Ceylon, what value at present would you put on this per acre?" I replied that coffee nowadays was not included in the valuator's figures. "Where's your cinchona? Let me see the tea How many tons of bark are you likely to harvest?" These are the style of questions put by a modern valuator in Ceylon. Let me plead for your old love, my brother planters. See her sister from Coorg willing and ready to respond to your loving care, as her now sickly sister ever did. You are in a country selected by young capitalists because everything was found. Coffee at first in its pristine vigour bore grandly, and great was the extravagance resulting from too great an influx of wealth. Now should you ascend again to similar heights of fortune, it will be with a steadier brain. The school of misfortune has taught you lasting lessons. Surely, with noble mills, and agency offices at the seaport; an already large staff of V. A.'s; splendidly roaded districts and estates; and a railroad now being constructed through these districts—*surely*, I say, it is worth while trying this new variety of coffee, and trying it honestly.

India. ABERDONENSIS.

[The Coorg variety has already been freely tried in Ceylon, but the last report on the coffee trees so grown was not favourable: how are they looking now?—Ed.]

A native remedy against attacks of land leeches is thus noticed in a report on the Boundary Line between Cochin and Coimbatore by Mr. A. W. Peet Deputy Conservator of Forests, Madras:—The followers suffered a good deal from the swarms of leeches all along the route. Of course, Europeans with ordinary precautions can defy them; but I should like to mention the Kaders' preventatives, which is useful as an additional precaution plastered outside leech-gaiters. The substance they use is called Koogamanjil (*curcuma aromatica* or *Zeodaria*). They powdor the root, which has a very strong aromatic scent, place it in a small bucket made of a section of bamboo, wet it thoroughly, and plaster it on their feet and legs with a brush made of a stick split and battered at the end. Leeches will not come near it.

Coffee in Brazil.—The municipality of Acarap'e Ceará, has freed all the slaves within its borders through gift and popular subscription. There were only 32 slaves in all, and through their liberation Acarape becomes the first free municipality in the empire. It is a distinction than which none can be more honorable. According to the *Rio Branco*, of Pirassununga São Paulo, the next coffee crop in that municipality promises to be very light. The *Gazeta* of Valença, Rio de Janeiro, says that the next coffee crop in that municipality is not very promising just now because of the drouth.—*Rio News.*

Shaving Cinchona.—Dolosbage, March 3rd.—Here is the result of eight days' shaving from *C. succirubra* planted in S. W. monsoon, 1880. The trees are therefore rising three years:—

Coolies.		Trees.		Wet Bark. lb.
5	...	835	...	682
5	...	795	...	778
5	...	870	...	644
5	...	719	...	625
6	...	835	...	720
5	...	858	...	838
5	...	662	...	622
6	...	889	...	725
Total...42	...	6,463	...	5,634

Average per cooly say 134 lb.; average per tree nearly 14 oz.—trees taken as they stand in the lines, big and little. May this be considered a satisfactory growth, and above the average? [It seems to us very good for such young trees.—Ed.]

Coffee in Brazil.—Renewed attention will be given to this subject now, and it is interesting to learn the opinion of a competent authority (the *Rio News*) on the late Mr. Crüwell's and on Mr. Scott Blacklaw's letters which we published in pamphlet form:—

We are in receipt of a convenient and valuable little volume published at the offices of the *Observer*, Colombo, Ceylon, entitled *Coffee Cultivation in Brazil: Its condition and prospects.* The book, which contains something over 150 pages, is composed chiefly of letters addressed to *The Observer* from Brazil by two wellknown Ceylon planters, Mr. G.A. Cruwell and Mr. A. Scott Blacklaw, but also contains much valuable information on Brazil collected from other sources. It was first published in 1878, and does not therefore contain the many valuable letters from Mr. Blacklaw which have been published during the last few years. The purpose of the book—that of giving the Ceylon planters all available information about Brazilian coffee production—is one which is worthy of the highest praise, and might be imitated here with the best results.

Divi-Divi.—We quote as follows from recent proceedings of the board of Revenue:—"The board having learned that Mr. Cardozo had a small Divi-Divi plantation that was turning out very well, Messrs. Whiteside and Wilson visited and inspected it on the 9th November 1882. Mr. Cardozo has about seven acres planted with Divi-Divi, all produced from seed from two parent trees, which are about 25 years old. These two trees produced last year 560 lb. of pods, which when sold realized R18-10-0 (nett). Mr. Cardozo stated that the price in the London market varied from £13 to £19 a ton. During the three bottest months of the year, the trees are occasionally irrigated, but they are extremely hardy and thrive best on that soil that suits the Babul (*Acacia Arabica*). The trees are planted in rows, 22 feet apart. Mr. Cardozo has had offers for the seed at the rate of R12 an ounce, and for seedlings natives are now offering him R6 a hundred. So far as information is available at present, the Divi-Divi is of great value in tanning, dyeing and making ink; for each of these purposes a different part of the pod is used. Mr. Cardozo showed the ink made from Divi-Divi. It is extremely black, does not clog or corrode the pen and does not fade. The board are decidedly of opinion, in view of the success that is attending Mr. Cardozo's experiment, that it is very advisable to encourage the cultivation of Divi-Divi as widely as possible. There are immense tracts of land throughout the presidency onw hich the tree would grow well. It requires very little attention, and the price that the pods and seed command in the market, even now when the great value of the product is not sufficiently known, is very remunerative. The board recommend that collectors be instructed to endeavour to stimulate the cultivation of Divi-Divi. The demand for it in the London market would increase, no doubt, with the supply." The Government have approved the recommendation made by the board.—*Madras Times.*

Weeds in the Cold Weather.—[They get rid of weeds on tea gardens in India, by hoeing them into the ground. From the following letter to the *Indian Tea Gazette* it appears that the theory of weeds being rather beneficial than otherwise, is entertained by superior intellects in India as well as in Ceylon.—Ed. T. A.]—Some planters maintain that it is best to allow a garden to be overrun with weeds in the cold weather: that hoeing is of no good until the early rains set in. Weeds conserve moisture, and I have an idea that it is perhaps a good thing not to hoe the garden in the cold weather, but let it lie in rather a dirty state. Will some of your readers kindly give me the benefit of their experience?

Cultivation of Tea in India.—A correspondent of the *Indian Tea Planters' Gazette* writes:—The following is my estimate of *cultivating* (as agents and planters understand) 100acres of tea.

	R
One hoeing Duffadar	100
Deep hoeing once, at 6/8 per acre ...	650
Light hoeing four times, at 3/12 each per acre	1,500
Filling up vacancies	250
Manuring and forking (20 acres) ...	150
Draining	120
Cutting jungle, &c....	100
Pruning	375
	R3,245

or R32-8 per acre.

Coffee Production.—The Chicago *Tribune* says "that some idea of the rapid growth of the coffee trade of the world may be obtained from the fact that the total production which was 675,000,000 pounds in 1859, has now risen to 1,300,000,000 pounds or nearly doubled. In Europe alone the consumption of coffee is said to have increased 240,000,000 pounds in the single year 1879. As for the producing countries it seems that Brazil now holds the first place with a total of 560,000,000 against 330,000,000 pounds in 1870. The emancipation of the slaves is, however, expected to lead to a falling off in the crop, unless the Chinamen and coolies imported from Asia should prove unexpectedly well suited for the work of cultivation. Next on the list comes the Dutch-Indian possessions, which export about 150,000,000 pounds, the British East Indies, now exporting over 140,000,000, and Venezuela, producing about 100,000,000. On the other hand, the Antilles Islands have long been declining in the scale. Jamaica does not supply half as much coffee as in 1805. Martinique has fallen still more entirely out of the race, and the Reunion coffee, which was once highly esteemed, and is still declared to be of excellent quality, finds no longer any market in Europe, owing to the unfashionable bitterness of its taste." [The bitter taste here referred to gives Ceylon coffee as pecial value to coffee roasters and mixers for it is required to be added to the acrid coffees to give them something approaching a tone. The above statement is very interesting from a grower's point of view, and if the Yankees obtain a free breakfast table, as seems somewhat probable, what the figures for consumption may advance to in the next 10 years in the United States would be a difficult matter to determine.—Ed.]

CEYLON TEA-PLANTING ENTERPRIZE.

About the year 1864, the late Mr. Mitchell of Kelburne estate, Haputale, then on a visit to Nuwara Eliya, pointed out to us a fine expanse of forestland behind Baker's Farm, which, if he had had the capital, he would fain have purchased with the view of opening it as a tea plantation. A practical agriculturist, Mr. Mitchell felt confident of the success of tea cultivation in the climate and soil of our hill districts, and had he not been fully occupied in opening the large Haputale plantation referred to, he would have readily begun at that early date an extensive tea plantation near Nuwara Eliya. About the same time, a wellknown Visiting Agent long acquainted with the districts around Gongalla and Adam's Peak, in one of his reports to the *Observer*, said :—"Mark my words, if the Western slopes of Adam's Peak do not, before many years elapse, present one of the finest expanses of tea cultivation in the world." If our friends were visit the districts around Nuwara Eliya and those usually known as the Southern and Peak stricts in the present day, they would feel that their prophecies were rapidly coming true. Save at one corner in the new Kuruwita district, it cannot perhaps be said that the Western and South-western slopes proper of the Adam's Peak range have, as yet, been invaded by the tea-planter. But from Kegalla right along to Morawaka, it may be seen that tea is now the predominant object of attention with the European planter and that in the palmiest days of coffee in average districts at least, the prospects of a fair return on capital invested, was not more favourable than it is today in the Yatiyantota, Awisawella, Kuruwita, Rakwana and Morawaka tea plantations. In confirmation of this opinion, enough has already appeared in our columns respecting the first-named districts and we have now pleasure in calling attention to the report on the latter of the experienced Indian tea planter who has done so much to improve and promote this industry in Ceylon. He writes as follows :—

THE RAKWANA AND MORAWAK KORALE DISTRICTS FOR TEA.

To the Editor of the "Ceylon Observer."

8th March 1883.

Dear Sir,—I promised to let you know what I thought of Morawak Korale and Rakwana as tea districts. I think the soil, rainfall and climate all that could be wished for the profitable growth of tea. Morawak Korale I consider the best of the two districts, but both districts are good, provided that the land to be planted with tea is well chosen. The two estates that I visited, Campden Hill and Anningkande, are about the best I have seen in Ceylon : the soil and lay of land are simply perfect, and the estates are carefully roaded, drained, and planted with a very good class of Assam hybrid. I have no fear at all but these estates can be worked up to 700 lb. of tea per acre in full bearing. Considering that I know of two lowcountry estates that gave 85 and 70 lb. respectively of tea per acre in the first month of this year and that had they been fully planted up they would have given more (and note that neither of these estates are yet in full bearing) and supposing that we could only manufacture 10 months of the year,—my "awful" estimate of 700 lb. per acre would be realized.

A better system of planting will have to be adopted in the Rakwana district as most of the estates now planted are very much exposed to the wind. With a system of closer planting, say 3×3, and allowing every third line to grow up for seed, the difficulty would be got over as the seed-bearing trees would form wind-belts and save the young flush from being damaged by the wind. The roads and drains also ought to be hedged with tea on both sides and allowed to run up, as wind-belts. I am glad to note that all the lowcountry estates are doing very much better than I anticipated in my wildest dreams, in respect of quantity per acre, and there is now no doubt but we shall yet see thousands of acres taken up for tea in the lowcountry of Ceylon.

I intend visiting Maskeliya next week, after which I will be able to give you my opinion on it as a tea district.

By the way I saw Mr. Shand's toy patent drier at work : the great objection to it as a tea drier is the escape of steam which would keep the whole tea store in a continual state of moisture, especially if one had 20 or 30 at work—a number which would be required for a very small estate. Besides you could not heat the machines without filling the store with smoke, which would taint the whole of the tea. As we are all making bad enough tea as it is in Ceylon at present, for goodness' sake don't let us seek for machines to make it worse.—Yours, CHA.

The "unfortunate proprietors" in the "Southern districts," once so full of hope over their coffee fields, but latterly inclined to regard most of their land as useless, may now find even in the Kukulu as well as in the Kolonna and Morawak Korales that tea carefully planted in the way pointed out by "Cha" will put a new face on their investment. Not only on the Adam's Peak slopes, and Gongala uplands, are there reserves available for tea but away in the lowcountry towards Kalutara, where a climate with abundance of moisture and sunshine will do much to atone for a soil inferior to that found in the majority of Indian tea districts. In the Kalutara district itself, even within the influence of the seabreeze, the success of tea cultivation has been demonstrated in the best possible way, by satisfactory sales of produce in Mincing Lane, and there can be no doubt that a good many thousands of acres can be judiciously selected between this point and Gongalla and Adam's Peak before it is said that the land in Ceylon fit for tea is exhausted. But meantime, we need not wander so far afield. It is satisfactory to know that in the old districts and adjacent to them, so much is being done in tea. The present season has shewn how profitable the cultivation of tea plants as seedbearers can be made : for in one case mentioned to us the gross return per acre seemed to be manifold that of coffee in its best days. The large quantity sold both of imported and locally grown seed, as well as of nursery plants, shews how widely tea is being planted and "Chas'" report cannot fail to encourage not only those directly interested in this enterprize, but also those who desire to see a revival of the prosperity of the Colony at large.

THE SUGAR TRADE,

judging from Paty & Pasteur's annual review, is suffering from over-production equally with that in coffee and tea. Beet sugar has increased rapidly under a system of bounties which has given the people of Britain cheap sugar at the cost of German taxpayers—all save the beet growers. We quote as follows :—

According to the Board of Trade returns the imports of sugar into the United Kingdom during the past year have been larger than ever, exceeding those of 1881 by fully 50,000 tons ; the consumption has remained stationary,

having reached about 980,000 tons, and as prices have ruled below those of preceding years, and the general state of the country has been fairly prosperous, we can only conclude that the consumption of the United Kingdom has reached a maximum for the present, and cannot be further stimulated by the low prices ranging.

The West India crops have exceeded the average of previous years, whilst the Java crop is the largest on record, about 270,000 tons being shipped in the season ending 30th June, 1882. Notwithstanding the large increase of steamer shipment for the Mediterranean, we have had the same quantity available for Northern Europe shipped to Channel for orders. The present crop bids fair to approach its predecessor, but was somewhat affected by heavy rains in July last. Shipments from 1st July to the 31st December, however, reach 200,000 tons (of which 97,000 tons to coast for orders and 72,000 to the Mediterranean for orders,) against 175,000 tons in the preceding season, 135,000 tons in 1880, and 115 000 in 1879. Contrary to expectation no increase has reached us from Cuba, although the crop was nearly 100,000 tons larger than in 1881. The present crop, first estimated at 650,000 tons but now reduced to 600,000, or the same as in 1882, will probably again find its way to the United States, where the consumption of sugar has increased by 72,000 tons during the past 11 months.

From Manilla we have received less than in 1881 only 60,000 tons being shipped to Europe to the end of November, against 108,000 tons in 1881, the totals to all ports being 132,000 tons, against 192,000 tons. For the present season we may see some increase.

The Brazils have sent us less in 1882 than in 1881, and this year's crop is again reported smaller, estimates varying from 15 to 20 per cent. decrease. The import into London of *Madras* sugar has reached 40,000 tons, against 31,500 tons in 1881. In addition to this several cargoes have gone to Liverpool and the Clyde. The imports by steamer have not given satisfaction and the quality of the cane *Jaggery* has been below the average of previous years. The present low prices do not seem to affect the prospect of supplies for the coming season. Generally speaking, if Europe is losing her grasp over the Cuba and West India crops, supplies from the East are not likely to fail, whilst the production of beet sugar is steadily increasing, particularly in Germany, where the premium arising to the fabricants out of the present mode of levying the excise and returning drawback on export is increasing the number of factories to such an extent that the producers themselves are agitating for a reduction of the bounty. The deliveries of sugar on the Continent, on the other hand, are hardly showing any increase, except in France, where the reduction of the duty carried out in October, 1880, is still acting favorably upon the consumption.

It is estimated that Germany has disposed of some 40,000 tons of her surplus production of the present season, leaving still about the same amount to be exported in excess of last year's supplies. The abolition of the 10 per cent. extra duty in the United States on indirect import of Eastern sugars, and the prospect of a general reduction of the tariff, may eventually lead to an improved business in our markets, as prices in Europe have now reached a very low level, and consumption in the United States has evidently not yet reached its maximum.

CARDAMOM CULTIVATION.*

There can be no doubt that the little pamphlet entitled "Notes on Cardamom Cultivation," by Mr. T. C. Owen, just issued from the press, embodies the most reliable practical information ever published on the subject. Nearly all that Mr. Owen puts forward is the result of actual experience, which is more we suspect than can be said by any other writer whom we quoted in our *pro tem.* compilation of "All about Cardamoms." In fact, the Ceylon planters in the case of Cardamoms (as in that of Indiarubber trees) may be said to be the pioneers of systematic cultivation in a land and on soils other than those which form the habitat of the plant. In the pages before us, Mr. Owen is as simple and terse as even the Dikoya Planters' Association could desire: he confines himself chiefly to the results of his own and his neighbours' personal experience, and endeavours to answer such questions as would be asked, and, indeed, have been freely asked, by intending cardamom planters. We do not mean to make extracts further than to refer to the Estimate of expenditure and returns on 25 acres of cardamoms (managed from an adjoining estate) furnished by Mr. Owen. He puts the value of the land at R100 per acre, and charging R15 per acre for clearing undergrowth and first weeding; R20 per acre for lining, holing, planting and supplying; R500 for superintendence; R1,125 for cost of 37,500 double bulbs, allowing 50 per cent for supplies and a sum for tools, roads and weeding, he makes the first year's total expenditure equal to R5.300; the second and third years would add R925 each to this amount; during the fourth year, a curing-house has to be provided, and the cost of crop gathering, &c., brings the outlay for this season to R3,100, making the total for the four years R10,250, while crop is estimated to give R6,875, leaving R3.375 to the debit, at this date. The expenditure in the fifth year is put down at R3,200 = R6,575, while the second crop should realize R11,437, leaving a profit of nearly R200 per acre. Those who wish to know how the 25 acres cardamoms garden is expected to yield after this must refer to Mr. Owen's "Notes on the Estimate," as well as to the rest of his useful and timely *brochure*.

* Notes on Cardamom Cultivation. By T. C. Owen. With an Estimate of Expenditure and Return for 25 Acres and Notes on the Estimate. Colombo: A. M. & J. Ferguson. 1883.

INSECT AND OTHER ENEMIES OF TROPICAL AGRICULTURE.

For some years past the government of the United States has been engaged in assisting the planters of the South in studying the insect diseases of the cotton plant and sugar cane, with the purpose of discovering some means to destroy them and relieve agriculture from the serious losses which it has been sustaining every year. In this work several of the best entomologists of the country have been constantly employed, together with a well organized corps of assistants. Besides these many volunteer investigators have been engaged in the work of studying plant diseases and have rendered invaluable assistance. It is estimated that the losses to agriculture since 1865 from the ravages of the cotton worm alone have averaged not less than $15,000,000 per annum, and it is now conceded that a very large part of this sum is saved through this work of organized scientific investigation. The character and habits of the insect have been carefully studied and long continued experiments have been carried on to determine what agencies can be employed to accomplish its destruction. Although it may be considered impossible to wholly exterminate the pest, still enough has been accomplished to restrict its ravages and to save a large part of this enormous annual loss of $15,000,000. To secure further data upon this investigation, as well as upon the insect diseases of sugar cane, orange trees, etc., the chief of the American commission, Prof. C. V. Riley, has sent out a branch commission to carry on a brief series of investigations in Brazil. This work has

been intrusted to Mr. John C. Branner and an assistant, who are now pursuing their investigations in the province of Pernambuco. Mr. Branner is already well known in Brazil in connection with the late Prof. Ch. Fred. Hartt's geological commission, and in connection with a subsequent search for a fibre suitable for the carbon arch in the Edison electric lamp. In this latter work he spent about one year in Brazil, and succeeded in finding the best fibre thus far used. For his present work Mr. Branner possesses unusual qualifications which can not be otherwise than of the greatest assistance to him. He possesses an intimate personal knowledge of a very large part of Brazil, a good knowledge of the language, and a good scientific training. With these it is certain that his investigations will be of high value, and will be of the greatest assistance to the American entomologists in their work of destroying the insect plagues of American agriculture.

In view of the fact that Brazil is almost wholly dependent upon the products of her soil, it would seem that the policy pursued by the United States in the study and extirpation of insect plagues is one worthy of imitation. At the present time there are three principal products, coffee, sugar and cotton, upon which these investigations could be made with great profit. Of course, the work can not and should not develve wholly upon the government; the planters themselves should join heartily in the work and give every assistance to scientific investigation. Already Brazilian agriculture has suffered incalculable loss from insect plagues. For many years both the coffee planters and the sugar planters have complained of the losses inflicted upon them by various kinds of pests but even yet no organized effort has ever been made to assist them. It is true that commissions have been entrusted with the work of studying these plagues, but they have either been entrusted to men who knew nothing whatever of the subject, or they have been crippled with instructions, limited time, and meagre appropriations. From investigations of this character it is idle to expect good results. No scientific man can make a flying visit to one or two coffee orchards at hap hazard and then tell us what kind of a disease it is which has afflicted the coffee plantations of S. Fidelis for the last dozen years; and if a scientific man can not do this, assuredly little can be expected from men who have mastered little more than the rudiments of science. Amateur work of this character is worse than useless, for it not only fails to give good results but it seriously misleads those who are prepared to accept the dictum of an official commission as law and to accept its conclusions without question. In the one case of coffee diseases, which affects the principal industry of the country, Brazil should have a permanent entomological commission, composed of thoroughly-trained scientific men, and charged with the most painstaking investigations. The little island of Ceylon has been doing far more in this respect than the great empire of Brazil. Then take the several diseases affecting sugar cane, which are spread over so large a part of the country, and we find abundant work of this character. It might cost a few contos a year, but if rightly constituted and encouraged it would be the means of saving thousands of contos every year to the agricultural industries of Brazil.—*Rio News.* [The "little island of Ceylon" is bound honestly to confess that the main result of all investigation and all expenditure as yet is a better knowledge of the life history of the deadly fungus known as *Hemileia vastatrix* and of the cockchafer beetles and their grubs, than of any means for stopping or even mitigating their ravages. "'T is true, 't is pity; pity 't is, 't is true."—Ed.]

THE INDIAN AND CEYLON TEA MARKET.

We beg to invite the attention of our planters to the remarks of a trade journal, *The Produce Markets Review*, on the importance of regulating to some extent the supplies of tea put up for sale by public auction. We have constantly called attention to the necessity for studying the capabilities of the market on the part of importers, and here we have a journal written in the interests of the trade pointing out the same thing, viz., that importers by hurrying their teas forward and printing them for sale, in some cases that have come to our notice actually before the teas have been seen by the brokers are sacrificing their own interests and *selling their teas at unnecessarily low prices.* A kind of panic to sell seems to have seized the merchants, and hence the large sales with their accompanying low values that we have seen during the last two or three weeks:—

The custom of offering teas without allowing a reasonable time for the trade to taste them continues, and in some instances large catalogues have been issued only a day or two before the sale. The tea cannot be dealt with effectively in such a limited time; and frequently even when there is a longer interval between the time the catalogues are issued and the sale, samples are not obtainable at the warehouses until the day previous to the advertiseed date of the auction. Unless, therefore' the importers arrange not to issue catalogues until the teas are actually ready for sampling, and then to allow at least two clear days for tasting and valuing, the difficulties of the past fortnight will increase, and the results cannot prove otherwise than prejudicial to the tea planters. At the public sales 23 343 packages were offered including 454 Ceylon teas. Fine teas were steady, and in some cases slightly dearer, but the lower grades sold in buyers' favour. No movement of importance has taken place in Java teas. There was an active inquiry at this week's sales for the Ceylon growths, most of which were quite equal to the finer Indian teas, both in quality and strength, and the prices realised also compare favourably. This will afford encouragement to the planters in the island, who are so much tried by bad crops and low prices of coffee. It will be an immense advantage for them to have another string to their bow, and to find employment out of the coffee season for any skilled labour they may have, while the ready transport to the coast gives Ceylon a great advantage over the Assam planters. —*Home and Colonial Mail.*

AGRICULTURE IN BRAZIL.

Rio de Janeiro, January 5th, 1883.

From one of our morning contemporaries which is giving a great deal of effusive attention to the special interests of the old planting classes, we learn that the state of agriculture in this country is most lamentable. With the threatened extinction of slavery and the decrease in the prices of coffee, the planters feel that their industry is seriously endangered, and that there is little for them to hope in the future. One of them writes that free labor (the *camaradas*) has been tried and has resulted in failure, for which reason the planters are abandoning their coffee orchards and are devoting their attention to food products. This, of course, has occasioned a widespread discontent, as the coffee industry represents both their capital and income, and it has also occasioned not a little of bitter complaint against those who have opposed the wanton bestowal of public funds upon one special industry. All this is to be expected. Critical as the situation is, however—and we do not underrate its extent or danger—we do not believe it to be quite as hopeless as pictured. The crisis through which the planting industries of Brazil are now passing is one which was inevitable, and, in our opinion, it can not be otherwise than most beneficial. Nothing else will purge Brazilian agriculture of the multitude of evils which have fastened upon it, and which are impassable obstacles to its full and free development. One of these evils is slavery. It is true that its extinction will bring not a little of disaster and confusion, especially among those institutions growing out of slavery and living upon its fruits; all these are inevitable. When, however, the great evil itself has

passed away and a system of free labor is firmly established in its place, these very planters themselves will by the first to forget the sacrifice and to wonder why they opposed so beneficial a change. Another result of the crisis will unquestionably be some modification in the system of agriculture now employed. The *grande lavoura* (great estates) of this country has clearly had its day and can no longer serve a useful purpose. It is now an absolute hindrance to development. It grew out of the employment of slaves, and with slavery it must pass away. Until that time comes, immigration will find no secure footing, and free labor no real encouragement. It is idle to talk of securing colonists through contracts to work the large plantations, for no such system can be even moderately successful. What Brazil most needs is a class of small farmers, owing and working their own lands; and these can only be procured after the extinction of the great estates which are now so fatal to all real agricultural development. If the crisis into which Brazil is now entering will hasten the extinction of these two great obstacles to her industrial progress, none of the sacrifices of which planters are now complaining will be too great a price for the service rendered. Instead of heavily mortgaged estates, administered by soft-handed idlers who run to the government whenever their credit fails, or their crops are injured, or the prices of their products become unremunerative,—instead of a class of this character, Brazil will have men who toil with their own hands, who will have no favors to ask except to be let alone, and who will look upon unremunerative prices for one product as a signal that something else must be tried. It is little to the credit of the planters of today that they find nothing else to do than the abandonment of their coffee plantations just because prices are low and slavery is doomed.—*Rio News.*

THE BEER OF THE FUTURE.

TO THE EDITOR OF THE TIMES.

Sir,—It may be interesting to your readers to learn that, owing to the partial failure of this season's English hops, together with a large demand to supply the American market, values have advanced to such an extent that substitutes are eagerly sought after in the Mincing-lane Market, and drugs which can, on account of their bitter qualities, be used in the manufacture of beer, have been in speculative demand to such an extent that in some cases the values have advanced 300 to 400 per cent. It has generally been supposed that beer could only be made "bitter" through the medium of the hop plant; but this innocent delusion must be given up, the laws of supply and demand having taught us that there are other plants not familiar to Kent or Surrey which can be used for the same purpose. Colombo root, well-known for its tonic qualities, has advanced in value from 22s, at which it was obtainable a month since, to 95s per cwt.; camomiles from 40s to 120s; quassia from £5 to £40 per ton; Guinea grains which have always been more or less in use for brewing purposes, from 32s to 60s per cwt.; and the most surprising of all, Cheretta, a drug which a month since was almost unsaleable at 3d per pound, has actually been sold at 3s to 3s 6d per pound. Most of these are very harmless bitters, but what a fine opening this must be for the Blue Ribbon Army advocates to set before their disciples, the composition of the "horrid mixture" called "bitter beer."—We are, sir, your obedient servants,

Joseph Brothers, Brokers.

10 and 11, Mincing-lane, London.

[Why is cinchona bark omitted?—Ed.]

What Causes Inferior Quality Teas?—My theory is that a tea bush, if not maltreated before the close of its fifth year, will stand almost any amount of maltreatment up to its eighth year, and during the period will give its maximum yield; but that, if in and after the sixth year one or two sticks are not cut down to the collar year by year for renewing the bush by bringing up fresh free-celled wood, the yield will be found to diminish, and the leaf be *bhanjee* and incapable of producing high quality teas after the 8th year.—*Indian Tea Gazette.*

The People of England use about 5lb. of tea a head every year to 1 lb. of coffee. In France the average annual consumption of coffee is about 40,000 tons, giving 3·53lb. a head. In Germany and in Holland the proportion is 5·3 lb. a head, in Switzerland 6·68 lb., and in Italy only 1·05 lb.; while in Belgium it amounts to 9 lb. a head, which is the highest figure reached by any European country.—*Friend of India.*

An India-rubber Oil has been patented in Germany as a protection against rust. It is produced by steeping thin strips of india-rubber in the rough oils obtained from the dry distillation of coal, lignite, or peat. Its further treatment is a secret, but when prepared a thin coating, painted over bright iron or steel, preserves it against oxidisation, by forming a dry skin, which lasts for a long time.—Melbourne *Argus.*

The Year 1882 in Brazil.—The internal state of Brazil at present is far from satisfactory. The fall of prices for the one great product of the country has caused much loss and anxiety among planters, and already there is talk of abandoning that industry. As a great part of the coffee plantations now producing are new, it is probable that very few will be abandoned and the production will be kept up. In the slavery question, however, lies the prime sources of danger at the present moment. Several isolated insurrections have occurred during the year, chiefly in São Paulo, where the planters are thoroughly alarmed. Nothing has been done to pacify the slaves and to improve their condition; on the contrary, there is a very apparent disposition among slaveholders to make the most of the remaining years of slavery. To that end they are worked harder than ever, few promises are held out for their future liberation and improvement, and they have the disturbing influence of a 2 per cent. per annum emancipation constantly before their eyes. Under such conditions discontent is inevitable. Aside from this question which forebodes a time in the near future when there will be no regular labouring element left on the plantations, it is noteworthy that no intelligent effort is being made either to retain the freedom on the plantations, or to secure a permanent labouring element through free immigration. Efforts are being continually made to obtain colonists, but the aim is rather to secure semi-servile labourers through long term contracts, than free labourers who will seek to own and till their own lands. In business the year has been disastrous to a high degree. A large amount of trade is always going on, but this has been very largely confined to articles of prime necessity. Brazil being an importer even of a great part of her food, there must always be a large volume of business done. Aside from this, however, the state of trade has been highly unsatisfactory. In the coffee trade there has been an extraordinary amount of business done in view of the state of the market. The closing prices of the year show a decline of over 25 per cent. during 1882, while the risks have been largely increased owing to the fickle state of foreign markets. Notwithstanding these facts, the export for the year has been enormous, amounting to 4,061,059 bags, or a decrease of only 156,541 bags from the export of 1881. The net results of this enormous trade has of course been greatly reduced, and planters are complaining that their industry has become unremunerative; but it is still the one great factor in Brazilian trade.—*Rio News.*

Correspondence.

To the Editor of the Tropical Agriculturist.

PEPPER CULTIVATION; LIBERIAN COFFEE IN THE SOUTHERN PROVINCE.

Udugama, Feb. 8th, 1883.

Dear Sir,—I send you herewith the notes I made on Pepper Cultivation at Singapore and Johore, and also the best means, as far as my experience goes, of cultivating it in Ceylon. I hope to see pepper cultivation largely taken up in Ceylon. I may say that I tested the amount of crop by getting a vine stripped and weighed. I took a fair average vine. Mr. W. Bailey, now in Johore, and Mr. Bagot, since returned to Ceylon, were present, and I had the benefit of Mr. Bailey's Chinese conductor to interpret my questions. The export of pepper, as you are aware, is a very valuable one from Singapore, and there are any number of situations in Ceylon where it can be grown just as well as in Johore. I have on some of my vines ripe pepper at 18 months old, but these are only a few exceptional ones. You will be glad to hear that, in this district, the Liberian coffee is looking very healthy and is remarkably free from leaf-disease, and far from shewing any signs of dying out: the oldest, over 4-years, is very healthy, and ripening all its crop. We have had several blossoms since the 6th of January.

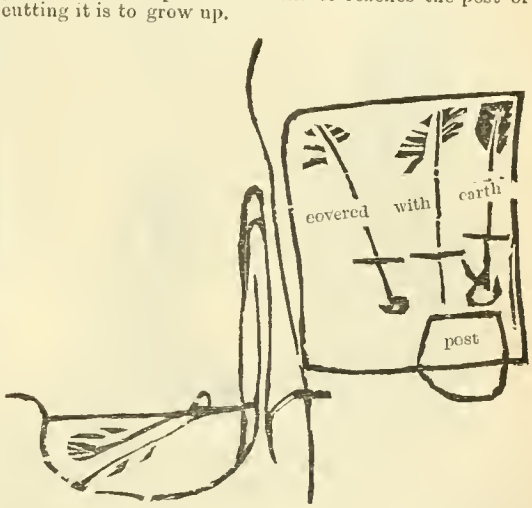
I believe the reason our Liberian coffee is so much healthier than the reports in your paper state it to be in other districts, is that our subsoil is deep and good, the top soil poor, and our Liberian coffee is all planted in *bona-fide* virgin forest. In Coffea Arabica's best days it never lasted in chena, except in Uva, and I am afraid a great deal of Liberian coffee has been planted in chena, and will go like Gampola coffee did in olden days. Liberian coffee is much more susceptible to harm from turned up or twisted taproots than even Coffea Arabica, and, if planters who have solitary trees that look sickly and won't ripen their crops, would pull up a few of these trees, I believe they would almost invariably find something the matter with their roots.—I remain, yours faithfully, T. S. DOBREE.

MR. DOBREE'S NOTES ON PEPPER CULTIVATION.

Line 7×7 feet; choose flat or slightly undulating land. If at all steep land is used, it should be *terraced* at once. Cut holes 2 feet square by 15 inches deep, and fill in with good soil free from all stones and roots. Don't heap up the earth when filling in the hole, but rather leave a hollow to catch all moisture. At the lower corner of the hole put in a post of split wood 12 feet long by 10 feet out of ground and about 8×8 inches square. This post must be of good hard wood, and have the end that goes into the ground cleaned and tarred. The vines at Singapore last for 20 or 30 years. I saw a garden said to be 30 years old, still bearing well, and the posts that had never been renewed were still standing.

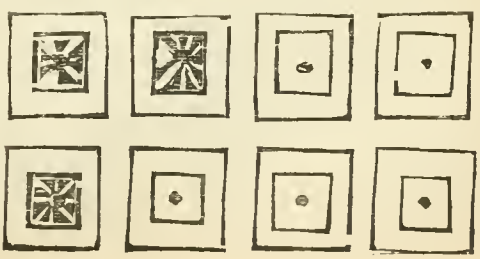
These posts are the most expensive* part of pepper planting, and I doubt, from what I know and what I have seen, whether they will be suitable for Ceylon, where white-ants are much worse than in the Straits; they no doubt, however, succeed admirably for the purpose in Singapore. When suitable posts cannot be obtained, I advise putting in cuttings 6 feet long of either "imbul" (cotton tree), "suriya," "enabudda," or "hikgas." I was told that the imbul or cotton tree is thought in Java to be the most suitable line tree to grow pepper on, and I find it the best down here. When the shoot from the cotton tree cutting or plant has grown to 10 feet from the ground, it should be topped and always kept as a pollard, both to prevent the pepper vine being shaded, and to keep the vine from running up too high. The cuttings must, of course, be put in in wet weather.

I also tried jak trees, putting in two jak seeds in every pepper hole. I found, however, that the growth of jak trees varies very much: some of my trees grown from seed put in in June 1881 were 5 or 6 feet high in December 1881, others were 1½ foot. Monkeys also pull out the jak plants, and crickets nip off the tops. I therefore consider cutting of the cotton are better, especially as they give something for the pepper vine to get hold of at once. Cotton tree plants can be used, and are easily raised from seed. When planting, put three cuttings or two good plants in each hole: both cuttings and plants should be 18 inches long when planted out. If plants are used, put their root end as far from the post as the hole will allow, and bury all the plant except the head and about 4 inches: this will cause the plant to throw out roots from all the buried points and increase its powers of absorbing manure. As the plant grows, keep it buried till it reaches the post or cutting it is to grow up.



Plant the cutting or plants about 6 inches deep and shade *well* with fern—or some suitable and cheap substitute.

The Chinese make a small mound round each vine, but I think in Ceylon, where we have heavier downpours of rain, it is better to cut small drains 1 mamoty wide and deep between *every* row (the usual 18 inch drains 1 chain apart must also be cut) both up the hill and across, so that every vine shall stand in its own space. The earth from these drains will form a slight mound round the holes, and into this hollow all manure should be put. The Chinese never dig in their manure but just lay it on the surface.

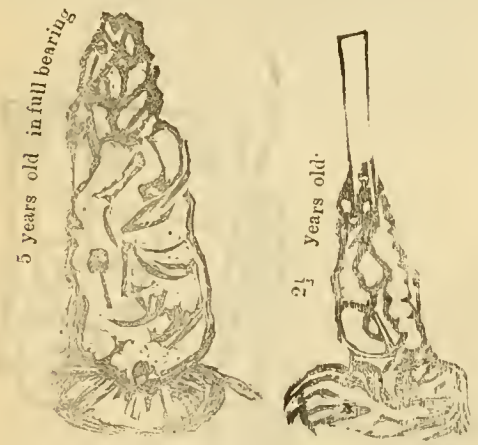


*From R70 to R150 per acre—889 posts per acre.

This work need not be done till the clearing is planted.

The Chinese commence manuring (with burnt earth chiefly) directly the cuttings are planted, and manure twice a year when they can afford it: once always. Burnt earth, cattle manure, fish and I think limes and punac would be the best. In some places, I believe in Sumatra, they let the vine run up to 5 feet, then take it off the post, and bury it in the ground, leaving the arch out of the ground, from which two or three suckers grow, and are trained up the post,

The Chinese in Singapore and Johore, who are said to be the best cultivators of pepper, do not do this, but plant their cuttings as I have described. They always use *cuttings*, and only the ends or tops of branches, which they put in a shaded nursery to root before planting out. I myself have found *plants* much more certain than cuttings and hardier, but I was not able to obtain cuttings of the ends of branches only. The vines commence to bear at 2½ years old. I saw a garden of this age in Singapore. The vines were about 6 feet up the post but bushy at the bottom.



and had a maiden crop on them. I can't estimate how much an acre, but I think it was about 600 lb. per acre.

From a good old average vine—said to be 30 years old—I saw 30 lb. of green pepper taken and weighed. I saw several gardens that I believe *averaged* as much as this vine.

As pepper dries down to one fifth of its green weight, this would be 6 lb. of marketable pepper, or at 889 vines per acre 5,334 lb. per acre for the autumn crop, and the Chinese said they got as much more for the spring crop. I did not see any spring crop, so cannot vouch for the truth of this total: say 10,000 lb. per acre per annum. I don't believe this.

The Chinese never, as far as I saw, plant more than from 10 to 15 acres of pepper in one garden along a carefully selected basin, and they cultivate each vine very highly, so that there are no bad vines in the whole acreage, until the garden is old and worn out.

A good average crop of pepper I have been told on reliable authority is about 28 piculs an acre or say 33 cwt., or rather over 4 lb. of prepared pepper per vine. The price of pepper in Singapore now $15 per picul, is very high, and I was told that $10 was a safe price to calculate on. This would give 28 piculs at $10=$280, or say about R600 per acre as the value of the crop, and putting down the cultivation at the extremest limit of R200 per acre per annum, leaves a profit of R400 per acre. This sounds almost too good to be true, but I feel certain these profits are made out of the pepper gardens in Singapore and Johore, and there is no doubt that the Chinese have made very large fortunes from this cultivation. The preparation is very simple. The Chinese use a very rough drying drier something like the ordinary Sinhalese lime-kilns with warachies on the top and matting on which the pepper is spread to dry with fire underneath. White pepper is made from the best and ripest berries. It is placed in heaps for several days to ferment and then trampled out and washed and dried very much in the same way as coffee. Pepper is sent to England in bags of 142 lb. each. It is taken at 16 cwt. to the ton for black pepper, and 18 cwt. for white. By using winnowing and sizing machines, I am sure we would very much improve on the samples of Singapore black pepper, especially by picking out the grey peppercorns, for which work labour is too dear in Singapore. *One penny* per lb. covers shipping, insurance, loss on weight (which is from 6 to 10 per cent), brokerage and freight. Pepper damages tea, and some ships refuse it. The lowest price it has ever been down to is $6 per picul many years ago. For the last five years it has averaged from $10 to $15 per picul.

A free rich soil is the best, and a continually wet climate. A long drought is said to cause the berries to fall off the branch before they are ripe. I could hear of no disease or blight that affected the vines, and certainly saw none on any of the many gardens I visited. The crop is picked with light step-ladders, the branches are picked whole, as soon as some of the berries begin to turn red and yellow. I don't think it possible to get all the berries on a branch ripe before it is picked: some would fall off before all were ripe. I consider good chena land, if not steep and washed, as better for pepper than virgin forest, unless all the logs and roots of the latter are cleared away, for it is extremely difficult to work up pepper as it should be done with the logs and roots on the ground. The vines that grow over the old *stumps* of large trees are always the finest, as they seem to derive nourishment from the rotting timber.

The 4th year's crop should quite cover expenses, but I cannot state the cost of picking and curing. I believe that for such districts in Ceylon as those round Galle, Awisawella, Yatiyantota and in fact all the south-west of the island, pepper will be one of the most remunerative products, if care is taken in selecting suitable localities for planting it. All ridges should be left in jungle so as to have plenty of earth available on the spot for using as manure when burnt. The Chinese pepper gardens are all surrounded by forest which, for about 2 chains from the pepper, have the earth for a foot deep at least all carried off during the course of years as manure.

I have forgotten to state that the vines should in no case be allowed to run up to the top of their post or pollard, until they have thickened out below. When the runner is 2 feet high the top should be nipped off to make it throw out laterals, and the vine should always be kept in the form of a sugar-loaf until it has got thick and bushy from the ground to the top of the pollard. If not stopped and made to thicken out, one single runner will get up to the top of the post or pollard in a year or 9 months' time and never become a good bearing vine.

We have now 130 acres of pepper planted at Udugama on 5 estates, all coming on well, and the land selected as nearly as possible in the same way as I saw done by the Chinese at Johore. T. S. DOBREE.

THE OLDEST CINCHONA TREES IN CEYLON.

Kirimadua Estate, Haputale, 8th March 1883.

Dear Sir,—On seeing your footnote to my letter on the oldest cinchonas in Ceylon, I walked over this morning to Gonamotava estate to verify the report I had heard of these trees being *non-seed bearing*. The *two* old trees * planted in 1862 were covered with small green fruit or pods, which Mr. J. Orchard, the manager, assured me would "come to nothing," as every one of the pods would "wither prematurely and drop off," the same as they had been doing for the last 13 years, in all which time, Mr Orchard told me, he had not been able to rear a *single plant by seed* from these trees, and I particularly noticed the absence of any self-sown trees or seedlings anywhere near these two *oldest* trees—and the fruit already *commencing to shrivel up and drop off prematurely*. The trees are growing on good black soil, and the surrounding coffee is excellent with fine crop, yet these *imported* cinchonas will not ripen their seed. This reminds me of a report of the late Mr. John Nietner, when planting out an experimental estate for the Baron Delmar, at Kadirana, near Negombo, on land purchased from the late Dr. Elliott (the father of the *Observer* and Sinhalese, as I have heard him called). On that experimental estate, intended by the Baron to introduce in 1852 other tropical cultivation into Ceylon than existed in those days, all the Egyptian, American and other varieties of cotton grew beautifully, blossomed, and fruited, but *all the pods dropped off prematurely* and never ripened, which Mr. Nietner put down to failure from "climatic causes"—something like Dr. Trimen now putting down *all* my friends, *the name less* hybrids, under the one generic term "Robusta"! "Abnormal weather" is a very convenient "term," but what sort of weather it is I really don't know. For the last two days we have had lightning, thunder and heavy showers. Today it is grilling hot and as fine as midsummer.—Yours truly.

JNO ATWELL.

* I measured these and found them 45 inches in circumference a foot from the ground, and over 30 feet high! This is good for poor "bleak and barren" Uva patanas.—J. A.

FIRST CINCHONA TREES PLANTED IN HAPUTALE.

Parate, Moratuwa, 9th March 1883.

Sir,—Mr. John Atwell is in error in believing that I uprooted the cinchona trees which he planted on Mahapittia estate He says it is necessary to mention names in order to put the saddle on the right horse, but he has put it on the wrong one this time.—Yours faithfully, ALEX. T. GEDDES.

TEA-DRYING AND MR. SHAND'S "PATENT."

Dear Sir,—My attention has been called to a paragraph in your issue of the 28th ultimo *re* Mr Shand's tea drier (which I saw at work on Barra estate, Rakwana) as having been approved by me, and that teas were valued at 2/ to 2/3. These valuations were for broken pekoe made in the usual way over charcoal fires. The teas I tasted, fired by the patent drier, had a nasty metallic taste about them, and, as it is well known that tea will not keep by being prepared with such a moist heat as steam, I am at a loss to know how such a statement could have been sent you for publication, holding as I do an entirely different opinion of the capabilities of Mr. Shand's patent. *I consider it practically useless for the manufacture of tea.* Fearing tea planters may be misled, I shall be obliged by your inserting my contradiction of the statement in an early issue of your paper. —Yours faithfully, W. CAMERON.

MR. SHAND'S PATENT TEA DRIER

Colombo, 12th March 1883

Dear Sir,—With reference to the remarks in "Cha"'s and Mr. Cameron's letters of the 8th instant, which appeared in your Saturday's issue, will you kindly allow me to explain that the little model referred to had only arrived on the Barra estate the day before "Cha"'s visit, and was put up temporarily in the tea-house? I intended it to be experimented with in a corner of the store verandah.

I need not point out to the majority of your readers that, in permanent arrangements for using large-sized machines, neither smoke nor steam need be allowed to enter the tea-house any more than in those buildings elsewhere heated by means of hot water, or in manufactories where steam is used, the smoke and escape steam-pipes being both placed outside the buildings. "Cha" is therefore evidently in error in stating that the machines could not be heated without filling the store with smoke or steam, and I me rather surprized that any one naturally supposed to possess mechanical knowledge should say so.

No planter desirous of adopting the principle of the models, for drying large quantities of tea, would think of doing so by means of 20 or 30 of them, instead of one or two large barbecue-shaped machines.

With regard to Mr. Cameron's letter the information I gave you as to the valuations was that furnished to me. I shall of course refer the difference in the two statements to my informant. If the galvanized iron surface imparts a metallic taste to the tea, the contact with the metal can be easily obviated by covering it with calico, a veneer of wood or something else, or by placing the tea on wire netting, as in the ordinary way, as I have previously suggested.

Mr. Cameron may be correct in saying that tea prepared with such a moist heat as steam will not keep, but, as steam is not intended to come in contact with tea made on my principle, I do not see how it applies to it. He is probably not aware that I have before me a most favorable report from the highest authority in Mincing Lane upon the tea I originally made by my method, and upon which the applications for patents were made and obtained. However, all those who have ordered models for Ceylon and India will no doubt experiment with them, in an intelligent way; and they will shortly be in a position to form their own independent opinions as to the value of the process, without being guided by the prejudiced ones of myself or anyone else.

I am sure you will do me the justice of admitting that I have all along recommended planters to ascertain for themselves at small cost whether the tea-drier has the advantages I claim for it, and not to accept as fact my verdict in its favour. I am quite content to wait the result. I am obliged to Mr. Cameron for the opportunity he has afforded me of correcting anything wrong. As regards his opinion on the quality of the tea made on the little model, his present account differs so materially from what my informant led me to state to you that I shall refer the subject to him, and allow him to reconcile the difference in the statements. Mr. Ross Wright sent me samples of teas made both on the drier, and in the ordinary way and attached to them Mr. Cameron's valuations, and he led me to believe that the quality of the tea made by the drier was very fine, as it really is, and that, subject to some modifications, Mr. Cameron thought well of the process. I do not think such a letter as Mr. Cameron's will do much harm. On the contrary I believe it will induce many persons to experiment and form their own opinions.—Yours truly,

C. SHAND.

P. S.—Extract from letter, dated 25th February, from Mr. Ross Wright:—"I have today sent 6 samples: a broken pekoe, pekoe, pekoe souchong dried on your small model which came to hand safely, and acts very well as far as I can judge at present, and a broken pekoe, pekoe, and pekoe souchong dried in the usual way. Mr. Cameron, who has been round this district and Morawaka, valued the broken pekoe dried on your drier, and the broken pekoe dried as usual on the stove from 2s to 2s 3d. This is very encouraging." Other evidence if necessary is producible in corroboration of Mr. Wright's statement that Mr. Cameron tasted the two samples, and I am told he could not distinguish any difference until he was told which was made on the drier.—C. S.

COFFEE PRICE AND THE OUTLOOK IN BRAZIL.

Sir,—Coffee-growing in Brazil is probably now receiving a severe check. A short crop with probably for some months to come only a very partial recovery in price will do a great deal to demoralize an already disorganized labor supply, which must be provided for out of some product, and if not out of the profits from coffee from what other product is the upkeep of slaves to come? Let me call your attention to R. B. T.'s writing in your Handbook for 1880 on this subject. He said:—

"Prices will always determine the question of supply. Supply will depend upon the means of supply. We have, therefore, to consider how the consumption is supplied, and how this contribution is to be continued. Cast our eyes over a map of the world. Experience has shown that coffee does not thrive productively, excepting within the inner tropical circles. By 'thrive' I mean yield productively contending with all contingencies. Let us take the map. How many centres of production are there capable of producing more coffee than all the world could consume. Central America, Guiana, West Indies, Liberia, with Africa generally, Arabia, Ceylon, all the islands of 'the Straits' region, great and small, Fiji, not to instance Borneo, New Guinea, &c.; but *where's the labour*? The key is *labour*. The cultivation of coffee must have labour, and that of a peculiar character: *minor* labour to cultivate—*major* labour to get in crops. Slave labour, however plentiful, being fixed, is fatal. It must ever be a condition of labour such as will afford a limited supply for cultivation, and an elastic draw for hands to pick. Any other condition will not suit. Else the burdens of hands out of crop must be too costly, while supply for picking in crop time is too few. Casting our eye over the map, there is no country like Ceylon in respect of labour, for we work our estates with whatever force we determine when we dismiss our hands out of crop, and regulate our advance for hands to come over from India to pick, according to our estimates of crop. India, adjoining our seaboard has a population of migrating labour of some eight or ten millions, out of whom we can draw some 200,000 crop hands, whom we dismiss with their earnings—to our relief, and to their own infinite benefit—to their homes, when crop is over. Where elsewhere do conditions of labour, such as these, suitable for coffee cultivation, exist? And a labour so suitable and so secure? It suits them and it suits us. So long therefore, as the Governments of India and Ceylon do not interfere injuriously (for interference must be injurious) with the influx and efflux of this stream of voluntary labour—so beneficial to the planter, so advantageous to the humble poor of India—so long as free currency is afforded to the natural adjustment of the supply and demand with its own preference of route—we, as coffee planters in Ceylon, or as employers of Indian labour for coffee, tea, cinchona, cinnamon, or cacao, or any other branches of industry, may bless ourselves that we possess a source of labour such as no other country of the world possesses for our peculiar demands. Such labour is the pivot upon which the question turns.

"Emigration from Europe will never succeed as directed to intertropical countries. Such emigration to Brazil to grow coffee will fail as disastrously as did that of Germans to Jamaica in 1836. What a vast field for supply of a most suitable labour there is in the hundred millions of industrious laborious Chinese—but they are for *number one*. Brazil is near to distraction on the question of labour to keep up their extensive cultivation. Sad for them—but good for us in Ceylon. No expedient can meet their condition. No inbringing of Germans, Portuguese, Maltese. They don't suit. Nor will their freed Africans suit. Nor will their own Brazilians suit, as labourers, to grow coffee, and gather in their crops. Notwithstanding the vast outlay on railways, and good capital laid out on apparently paying bases, they must come to a close on the question of labour as coffee growers. What gigantic visions come before us when we contemplate Brazil collapsing on the question of labour! We return to Ceylon with its labour resource. If we require Ramasamy we shall get Ramasamy, as long as we can afford to give him rupees, annas and pice.

"Endless resource of virgin forest for extension by surplus slave labour out of crop has resulted in a boundless expanse of planted land, for the gathering of the crops of which there is not sufficient labour, nor can it be found. Borrowed capital, got on a superficially glossed surface of apparent, and for the time ardent, prosperity, spun out a system of railways, and afforded the Brazilian the means of getting to the Barcadere his produce, to exhibit a momentarily manifest prosperity, but it was all on borrowed capital which had a basis of very questionable security, namely, slavery, and the

issue of slave labour. Labour collapsing, what comes of the security upon railway debentures? What for that of the borrowed capital? What of all securities connected with the coffee enterprize of Brazil? Let those concerned consider these questions, and, if possible, provide for them. I am merely considering how they affect the question of the supply of coffee to the market of the world, and next how this touches the value of estates in Ceylon. Six-and twenty years ago I concluded that the slave trade from Africa being declared piracy by Brazil, and various influences being in direct action upon the slave stock within the Empire, such as all children of slaves being free, and facilities afforded to slaves for purchasing their freedom, the day would not be distant when collapse must follow for lack of labour. But there followed an uncalculated action—mortgagees of slaves working in Bahia, and generally in the north of Brazil, on cotton, finding that the labour of these slaves, if sent south of Rio and employed in the coffee industry, would pay far better, had them transferred to Santos, &c., and employed in coffee cultivation and extension. Of course the consequence of this would be to put back difficulty or collapse, on the score of labour. And another element came in The Brazilians were not slow to see that every adult set free for culture was a gain. Before they had railways, they had to employ from 80,000 to 100,000 mules to work their transport, which we may assume involved 100,000 slaves to work these animals, and grow their food, &c. These have been liberated for employment on the coffee *Lavoura* since 26 years ago. And, moreover, if we grasp the fact that a vast extent of land most suitable for coffee has been, by hook or crook, planted with trees which are not pruned nor cultivated, but which in a state of nature, though left to contend with weeds, continue year by year still to throw a stream of coffee upon the market of the world, we must see natural and sufficient reason for postponement thus far of the collapse, which I consider is inevitable in the end. The slaves dying off, sources of liberation increasing the proportion of free blacks, the time must precipitate itself with something of revolutionary force, when the Government of Brazil will not be able to enforce the remnant of slavery in the Brazilian Empire. What then?"

At the time R. B. T. wrote the above (December 1878) Java coffee was at 42 cents.—Yours truly.

HOPEFUL.

MR. HALLILEY ON WEEDS.

Dear Sir,—As the governor of a steam-engine regulates the steam, so weeds regulate the moisture to the coffee tree. In all my letters I said a carpet of weeds. I no more believe in not weeding than you do, but I believe in keeping a carpet of weeds by pulling up the big weeds and mulching the roots of the coffee tree or burying the weeds as the weeding is done, without favoritism, and carrying the weeds to the compost heap and then giving it to a favored few. Weeds regulate the moisture by absorbing any superabundance in wet weather, and by keeping the soil moist in dry weather. If it was not for weeds, would the Ouchterlony Valley estates have been the best paying estates in the world and how comes it that, previous to clean weeding, Ceylon estates paid, when coffee was as many shillings a bushel to what it is rupees now? After clean weeding what came over the old districts, with the exception of a few estates that had substitutes for weeds? What came over Kurunegala, Matale, Rakwana, Kadugannawa, &c., &c. Take old Kabragalla above Nawalapitiya. It used to be a fine old estate and in 1874 (I think) was advertized for sale, and the advertizement stated that it never had leaf-disease. It was purchased for £15,000, and then clean weeding was insisted on, and now what has become of the once fine estate?

The substitutes for weeds are first boulders and stones, next thatch and last water-holes. Boulders and stones can only shade the soil, and prevent the drying of the moisture; they cannot regulate it. In England the farmers remove all stones out of their land, as they have a moist climate and do not require the soil shaded; in Spain the farmers retain all the stones, and, when asked the reason, lift up a stone and point to the moisture. Spain being a warmer climate requires more moisture than England. In the countries where they cultivate oranges to any quantity, they grow lupines in between and mulch the roots of the orange trees with them. Thatch is about the same as boulders and stones. In 1858 I visited poor Whittaker on Sembawatte in Yakdesas and he showed me some coffee he thatched and you could not wish to have better looking coffee or better crops, but it was too expensive to carry out to any extent. Water-holes simply retain the rainfall and force it to soak into the ground. In 1872, after a fortnight's rain, I put on people to plant my second clearing, and I was greatly surprized after so much rain to find that the soil in the holes was quite dry, which is proof that on clean land the rainfall does soak into the ground. Coffee wants a certain amount of moisture, coffee always looks its best in the rainy season, and coffee is always better on a hollow than it is on a ridge. Is there anything in the world cultivated as we cultivate our coffee, and is simply keeping the ground clean and reducing our trees to a nicely arranged framework cultivation? No, it is fighting against nature.

There is nothing new under the sun: there is no such thing as spontaneous production and in reality there is no such thing as hybridization. A half-caste or a creole botanically speaking is a hybrid, but in reality are the same animal man, and man has so adapted himself to localities that if he were plants or trees he would hardly be recognized as the same species. So it is with plants or trees: they will only mix or hybridize with their own species, and they have so adapted themselves to localities as often to be mistaken for something new. So that leaf-disease is nothing new, is not spontaneous and is not a hybrid: it is something very old, something that must have existed in Ceylon long before coffee was introduced, and must have attacked the first shuck or neglected coffee tree in Ceylon but was not noticed. If a tree takes up too much moisture without a sufficient quantity of essential food, the result is mildew and if the tree cannot take up a sufficient quantity of food for want of moisture, the result is mildew, so that leaf-disease is nothing more nor less than mildew adapted itself in a different form in the locality. Mildew is yellow in the coffee, vine, castor, pineapple and other plants, it is white in the orange, is ash-colored in the rose tree, and is almost black in some trees, and the cure for mildew is light, a sufficient supply of essential food and a regular supply of moisture, and how is the moisture to be regulated without a carpet of weeds?

—I remain, yours truly, G. F. HALLILEY.

[We regret that this letter should have got mislaid and so been delayed.—Ed.]

COFFEE PLANTING:—WEEDS; STRIPPING LEAVES AND LEAF-DISEASE.

Dear Sir,—Though rather late in the day, permit me to make a few remarks on some points that have been lately discussed in your columns.

1.—Weeds but slightly exhaust the soil till they begin to seed, and *then* the mischief begins. Could they be dug into the ground before seeding the soil would be enriched rather than impoverished. This digging however involves too much time, labor and money, with also the risk of wash. The system of merely hand-pulling the big weeds on a dirty estate has often been tried and never found to answer, as the white weed soon gives place to grass and other spreading weeds, which do harm and must be scraped off.

2.—Some 18 months ago I tried pulling off all the leaves of a coffee tree as a remedy for leaf-disease. Several of the primaries blackened and died off, others threw out foliage, which within about a month's time became infected with disease. It does not seem to be generally known that when a coffee leaf is pulled off no other grows to take its place: a branchlet, not a leaf, will spring from the point.

3.—Undoubtedly leaf-disease has in most places been milder this last twelvemonth, but there are some marked exceptions, and the generally comparative immunity is doubtless due to the absence of crop—a cause which I trust will not be again repeated.—Yours truly, K. C. B.

Decaying Lombardy Poplars.—The decaying state of Lombard Poplars is extending to the North as well as in the neighbourhood of Devizes. In the South-west of Scotland scarcely a healthy tree is to seen this year, and many of all ages, from twenty to fifty years old and more, seem in a hopeless state. The number of them in the district is not great, and wherever planted they seem much in the same state. If they do not recover and continue to grow, it will be a serious loss, as they appeared in many situations a most valuable tree to plant.—W. H. M. in *The Gardeners' Chronicle.*

Planks from Straw.—A Home contemporary tells us that a process has been discovered in America by which planks can be manufactured from straw, and in Chicago a building six storeys high and occupying an entire block is being erected for the new industry. The board is manufactured by converting straw pulp into thin paper like sheets, which are passed through a bath containing certain chemicals in solution. They are then subjected to enormous pressure, and finally to a thorough drying process. By superimposing a number of sheets and incorporating them into one in the pressing process, boards of any desired thickness up to the capacity of the machinery employed may be produced. The finished article, some specimens of which have found their way into trade circles in London, appears as compact as ironwood, while it is nearly fire and water proof, and it is susceptible of being sawed, planed, or worked as wood. Three tons of straw, the average yield of an acre of ground—will make 1,606 superficial feet of board one inch in thickness.—*North China Herald.*

Ivory.—Sheffield cutters and cutlery manufacturers attended in unusually large numbers the first sales for the quarter at London. There were offered 129 tons, including 35 tons from Bombay, Zanzibar, and Mozambique, 46 tons from Egypt and Malta, 10 tons from the Cape, and 28½ tons from the West Coast of Africa, Lisbon, &c. There were also 3½ tons of sea-horse teeth, 2¾ tons of mammoth, and 3¼ tons of cuttings and waste. It was generally expected that after the Egyptian war ivory would come as freely as ever from that country. This expectation will probably be disappointed. One of the London brokers has been to Egypt, and through his arrangements there was a fair supply; but he states that for six months to come Egypt will not supply any ivory. It is supposed that it is heavily mortgaged, and can only be released as the owners are financially able to meet their engagements. Never has there been such poor Egyptian ivory offered in London. The buyers state they were at a loss how to value it on account of its great age and poor preservation. Prices ruled about the same as at Liverpool. Billiard-ball and bangle sorts were a little easier; "hollows" of all descriptions were dearer; small tusks fetched full rates. Best African was easier; common quality fetched generally good prices. The Egyptian ivory, poor as it was, sold for £750 per ton Prices advanced as the sales proceeded, and some 10 tons were withdrawn at higher prices than prevailed at the outset. Dr. C. B. Webster, the American Consul at Sheffield, in a recent report presented to his Government, directed attention to the large proportion of very small tusks brought to market. This, of course, indicates how many elephants die in early youth. To show to what size many of these might have attained, Messrs. Joseph Rodgers & Sons (Limited), Sheffield, exhibit at their show-rooms an African elephant's tusk 9 feet long, 21 inches in girth, weighing 160 lbs. This is among the largest tusks on record. Its present value is 650 dol. Dr. Webster remarks than an animal large and strong enough to carro such a pair of incisors would would attract more attention than Jumbo. It is estimated that the 5,286 tons of ivory imported into Great Britain during the nine years from 1873 to 1881 inclusive represent 296,016 pairs of tusks, and, consequently, the same number, of elephants that have died or been slaughtered to supply the demands of luxury for the past nine years, At this rate of destruction, it is clear that the noble elephant most rapidly disappear, and ivory become a thing of the past, unless the traveller of the future should reveal fresh sources of supply on a vast scale,—*Public Opinion.*

Coffee Prospects in S. India.—Our correspondents writing from the Shevaroys and Coorg do not give very encouraging reports of the growth of coffee in those parts and, consequently, prices have gone down. The yield has not been as large as was anticipated and the dull state of the English market which regulates prices in all the producing tracts intensifies the present unfavorable state of affairs. On the Shevaroys the smaller estates appear to be doing better than the larger ones and the reason for this is not far to seek. Efficient supervision is, as a matter of course, exercised over the smaller plantations and though a short time ago efforts were made to improve some of the larger estates by importing new machinery, expensive manure, and adopting all the means which often lead to success, still they have not realised the anticipations entertained. In Travancore and in parts of the Tinnevelly district increased attention is now given to the growth of coffee. Coffee prospects in the Nilgiri district, we are glad to learn, are just now pretty good. The blossoms promise well. If rain falls, damage is likely to be done to the crop.—*Madras Standard.*

Poisonous "Pepper."—The following refers to the sale of a compound described as "black pepper dust," which since it was admitted to contain nearly 50 per cent of mineral matter, ought, in the public interest, never to have been placed in the market at all:—"Dowgate Upper Dock, Thames-street, E. C., January 24th.—Sir—About 30 tons of an article described in the catalogue as 'pepper dust,' was offered at the public sales in Mincing Lane a week since, when we ventured to call attention to the fact that the samples shown were flavourless and quite destitute of the pungent qualities of pepper. The selling brokers offered to withdraw the lots for the purpose of obtaining an analysis, and accordingly the same parcel was again submitted for competition at the weekly spice sales yesterday, the lots being marked 'without reserve,' with the following prefix:—'Copy of analysis made by Mr. Ogston:—Whole grains of pepper, 1·00; pepper leaves, husks, &c., 54·80; sand and clay, 44·20; total, 100·00.' The proportion of 'foreign mineral matter' appeared quite sufficient to condemn it as an article of food, and in the hope of arresting the evil at its source we proposed a resolution as at foot. It was put to the room by the selling broker and carried. He jocosely remarked that the pepper dust could be used for chickens, and he should, therefore, proceed to sell it in spite of the resolution. The whole quantity was accordingly sold and realized an average price of about £17 10s per ton. Possibly the pepper dust may go to feed fowls, but should it reach the hands of unscrupulous dealers, we fear the public interests will suffer. It is only fair to mention that the representatives of all the leading spice houses expressed a strong feeling against the proposed sale.—Yours W. and D. Harvest.—Proposed by Mr. Daniel Harvest (W. and D. Harvest), seconded by Mr. Bryne (Peek, Brothers, and Co.):—'That, inasmuch as the 608 bags pepper dust contain 44 per cent. of sand and clay, and would, therefore, subject retail dealers in the same penalties under the adulteration of food act, the buyers present protest against the proposed sale.' "—*Home and Colonial Mail.*

HARVESTING CINCHONA.

Several planters having expressed surprize at the figures lately given by a Delosbage planter for the daily average shaving of red bark trees by his coolies, as being so much more than usual, we referred the same back for further report. The result shews that there was no mistake in the figures. Our friend writes:—

"42 coolies got 5,634 lb from 6,463 trees planted in June 1880 and consequently *rising* 3 years. Of course I naturally chose a period when the coolies had got their hands well in (average for first four days was only 66) and when they were operating on the best piece in the clearing. I have now finished the field and give you the totals :—Extent of clearing 25 acres, 24,346 trees, 18,772 lb, 156 coolies, average per tree 12·33 oz. average per cooly 120 lb. Planted in June 1880; shaving commenced 26th January 1883 ; finished 7th March. Average age therefore two years eight months. Of course, you may furnish any sceptic with my name, though I did not send it for by publication with my letter."—We suspect that here we have the largest crop of cinchona shavings ever harvested from the same number of trees in so short a period. Delosbage should be the paradise of red bark trees.

THE PROSPECTS OF INDIARUBBER.

(From our London Correspondent.)

I had a long talk recently with Mr. J. H. Roberts, of the firm of Messrs. S. Rucker & Co., on the subject of *indiarubber*, a friend of mine having told me that he should be obliged to give up a large portion of his manufacture—*i.e.*, insulated telegraph wire—if he could find no fresh source of indiarubber supply. And he added : "The extension of our business which could be made, if such further supply was obtainable, you can hardly realize." He was prepared to largely extend his manufacturing plant but for this disability; but, as he argued, "where would be the use of my going to that expense, if, when incurred, I am landed in a difficulty for want of the material to be worked upon ?" Mr. Roberts told me so much that was of interest as to the market position of indiarubber in London that I asked him if he would kindly—as on a previous occasion he did with reference to cocoa—let me have his remarks in such a form that I could submit them to your readers. To my application he kindly consented, and the following is what he has written for me on the subject :—

"The adverse circumstances which have so forcibly operated during the past few years against the yield of the coffee crops in Ceylon have tended at all events to stimulate efforts to develop the capabilities of the island in the production of other articles, to many of which it seems to be admirably adapted. At the same time, it would be taking too gloomy a view to suppose that coffee in Ceylon is to be a thing of the past.

"While tea and cinchona are certainly the two largest articles which are following coffee, cocoa and indiarubber (caoutchouc) demand an amount of attention which they should certainly have given to them, and the efforts already made for their cultivation should be strongly further encouraged. With regard to the latter (indiarubber) there is no doubt that with due care its cultivation would become remunerative. The existing increased demand for the article throughout the world, the present supplies are anything but adequate to meet ; nor is there any reason to doubt, if there were a certainty of increased supplies, that the demand would still be further extended. Evidence of such increased demand has developed itself during the past two or three years, and prices have materially advanced ; those for Pará rubber, which ranged for a long time in the neighbourhood of 2s 2d to 3s per lb. having during the past year been gradually advancing, and, after touching 4s 10d and 4s 11d, are now still at about 4s 5d per lb.

"It is not intended in offering these observations to attempt any instructions to planters as to the best species for growth, cultivation, or collection, as these items so much depend upon the nature of different districts, and can better be ascertained through sources which, like the *Tropical Agriculturist* of Ceylon, have already most ably treated the subject.

"Great stress has been laid on care being taken not to incise the wood of the tree, but only the bark. One important feature, however, from a commercial point of view, may be here mentioned, and that is to collect the rubber as *clean* as possible, so that it may be free from bark and dirt, which are two most objectionable things, by the presence of which the value is most injuriously affected. Pará rubber deservedly stands highest on the list, as it possesses all the properties requisite for its use in the highest class of manufactured articles, and its cleanliness also entitles it to the standard it occupies.

"Attention is also much directed in the London market to Madagascar rubber as possessing qualities which are much appreciated, and some excellent sorts have also reached here from Upper Assam. Experience, with time, can alone develop which sorts are best suited to Ceylon, but up to this time it would appear that the 'Ceará' descriptions promise the most favorable result. Samples already received from Ceylon approximate Ceará scrap rubber more than any other kind, and this is now worth 3s per lb.

"It is certainly well worth the attention of all those who have invested capital in Ceylon and who seek a handsome remuneration for their investments not to neglect so encouraging an article as caoutchouc, or, as it is more generally known, indiarubber. It is to be feared that the rough treatment to which the tapping of the trees are subjected in some of the South American districts will ultimately render supplies from that quarter even more precarious than at present, as collection further inland must necessarily add to its cost. In this we have another reason why this industry in Ceylon will be beneficial, both to the grower and the consumer, an exemplification of similar mutual benefit being already given by the locally grown cinchona, which is most successfully competing with South American barks."

Remarks of the above character from one of the partners in a firm of such standing as that of Messrs. S. Rucker & Co. will deserve attention from those who are now commencing the culture of indiarubber in Ceylon. We all here at home read with the greatest interest all we can find in the *Observer* and the *Tropical Agriculturist* which informs us as to the progress being made with it. As yet this appears to be slow, but it is hoped things will soon take a rapid start.

Indiarubber.—We call attention to the very encouraging report on the prospects of this product contained in the letter of our London Correspondent. We are hopeful that Ceylon will do a good deal ere long to supply the demand for the raw material. But, meantime, have planters generally noticed what a keen observer reports that there are Ceará rubber trees ——and Ceará rubber trees ? That is, some of these now growing in Ceylon do not seem to yield rubber at all, while others give an abundant supply considering their age. This point requires careful examination in order that trees of a poor or utterly bad type may be pulled out.

MANILA NEWS : EXPORTS.

(Translated from Spanish newspapers for the "Strait Times.")

The *Comercio*, in reviewing the export trade from the ports of Manila, Cebu, and Iloilo, last year 81, 21:

that, from the prevalence of cholera, hurricanes, and other unfavourable circumstances, the exportation of sugar, hemp, indigo, coffee, pearl shell, and copper was less than in 1881, while that of dyewood, cigars, Manila rope, hides, and gum mastic, shewed an increase. The pearl shell exported from these ports fell off from 1,192 piculs in 1881 to 377 piculs in 1882, owing to that article being now shipped direct from Sooloo to Singapore. The decline in the coffee exported is ascribed not only to hurricanes but to discouragement among native growers, owing to the fall in the prices of that article, the consequence being that the quantity exported has, within the last few years, been almost stationary, as will be seen form the following figures :—

81,039	piculs	in	1882.
86,682	,,	,,	1881.
83,999	,,	,,	1880.
64,391	,,	,,	1879.
38,782	,,	,,	1878.

Pineapple Fibre.—A correspondent asks :—"Is there a market in London for 'pineapple fibre'? You were speaking in your columns of a machine for preparing aloe fibre. Will it answer for pine-apple? What will it cost to get one?" There is scarcely a plant fibre more valuable than that of pineapple leaves. The finer portions have all the qualities of silk, while the coarser are fitted for ropes and cables. We do not at present know the cost of an Ekman machine, but we hope soon to learn. No doubt the machine which answers for aloes would suit for pineapple leaves, but we fear the machine is somewhat costly.

Gigantic Trees.—The *Lumberman* has an article on the gigantic trees of Australia, of which the following is an extract :—"The trackless forests in the westof Tasmania contain huge timber, and bushmen report that they have met with specimens of *eucalyptus* measuring 200 feet from the ground to the first branch, and fully 350 feet in all. Until 1873 there was standing on the eastern slope of Mount Wellington, within four miles of Hobart Town, a *eucalyptus* measuring at 86 feet in girth and more than 300 feet in height, and its ruined boll still forms a grim chamber in which many a merry party have enjoyed a picnic. The famous tree of the Huon forest measures 70 feet in girth, 6 feet from the ground, and is stated to be 240 feet high, but in the deep gorges of this grand forest the writer has seen higher trees than this, though not of quite equal circumference. But Victoria now claims the glory of holding the biggest of all the living 'big trees' in the world, so far as the height is concerned. In the Dandenong district at Fernshaw, has recently been discovered a specimen of *eucalyptus amygdalina*, or almond-leaf gum, which has been accurately measured as reaching the enormous height of 380 feet before throwing out a single branch, and 430 feet to the top, and having a girth of 60 feet at some distance above the ground. Some idea of what a height of 430 feet represents may be gained from the fact that this gum-tree, if growing by the side of the Houses of Parliament at Westminster, would overtop the Clock Tower by exactly 100 feet." It is distinctly stated in works on Victoria that a prostrated *E. amygdalina*, with the top broken off, measured over 474 feet. The top would probably make up the round 500 feet. But a man like Dr. George Bennett is still sceptical. Baron Von Mueller, however, who ought to be the best possible authority, accept as correct, measurements approaching 500 feet.

Aloe Fibre.—We have been favoured with a sample of Ceylon Aloe Fibre which sold last month in Mincing Lane at £25 5s per ton. We have several samples by us prepared by local experimentalists, equally good in appearance and strength, but this price can scarcely be profitable if, as Mr. C. Shand found, the proportion of clean fibre got from the aloes is only 2 per cent.

Seasons and Coffee Crops.—Mr. Giles F. Walker does not wish to be credited with saying that the short coffee crops of the past three or four years have been due to abnormal seasons only. Mr. Walker certainly considers that low temperature and insufficient sunshine and warmth have had much more to do with the past bad seasons than is generally admitted ; but he does not leave out of sight the damage occasioned by leaf-disease, nor the fact that we have to face in future far smaller coffee crops in any season than we were formerly accustomed to expect.

Coffee and Cinchona.—The following cost of mixtures of coffee and chicory may be interesting to our readers :—

Wholesale selling price of roasted coffee per lb.	What the mixture costs with the undernoted proportions of chicory at 3½d, and expenses at 2d per lb.			
	Cost with 20 per cent of chicory per lb.	Cost with 40 per cent of chicory per lb.	Cost with 60 per cent of chicory per lb.	Cost with 80 per cent of chicory per lb.

8	9	8¼	7¼	6½
9	10	8¾	7¾	6¾
10	10¾	9½	8	7

Cocoa Drying : a chance for Mr. Shand.—The following paragraph is from the *Trinidad Chronicle* :—The Secretary of the Cacao Planters Association lately sent to England a draft for £50, the cost of a model cylinder for the artificial drying of Cacao in the wet season or bad weather. When the system proposed has been thoroughly tested, it is intended, to get out a larger machine, to do the work of an extensive estate. The present machine will be the property of the Association obtained for experimental purposes, and to ascertain what alteration, if any, it may be advisable to make in machines manufactured for estate-use on the scale of practice. Mr. Gibbs, Co. Essex, to whom is confided the make and fitting of the machine, is a gentleman who has bestowed a long and special attention of some years on the perfecting of machines for drying grain and fruit.

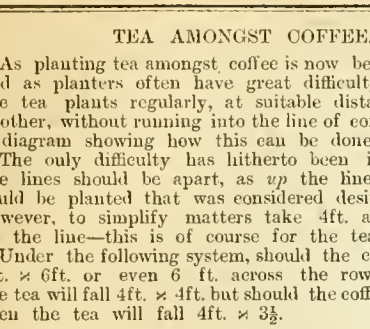
Silk in California.—In its retrospect of the trade of California for last year the *San Francisco Chronicle* says of the silk industry, in the State :—No progress has been made in the manufacture of silks during 1882,for the very competent reason that the works of the company were burned to the ground on the 9th of June last. All the machinery was totally destroyed on that occasion, and its reconstruction is not yet completed. Meanwhile the California company disposed of its interest to an Eastern concern, which is the owner of many valuable patents. The latter is now preparing to re-erect the works, which will be fitted with the most improved machinery. When completed, about seventy people will find employment at the silk-spinning works. The raw material which the California company handles is imported from Japan, China and Italy. The agitation of the Silk Culture Association in this State has not led to any practical results, though all possible encouragement has been given, the manufactories offering to purchase all California-grown silk at an advance of 25 per cent. over New York prices. A moneyed Frenchman who was attracted by the glowing pictures painted by the Silk Culture Association, and who went into the silk-worm business in earnest, found, after a short trial, that success could not yet be attained in California.—*North China Herald.*

TEA AMONGST COFFEE.

As planting tea amongst coffee is now becoming general, and as planters often have great difficulty in getting in the tea plants regularly, at suitable distances from one another, without running into the line of coffee, we publish a diagram showing how this can be done.

The only difficulty has hitherto been in the distance the lines should be apart, as *up* the lines any distance could be planted that was considered desirable. We will, however, to simplify matters take 4ft. as our standard *up* the line—this is of course for the tea.

Under the following system, should the coffee be planted 6ft. × 6ft. or even 6 ft. across the row and 5ft. up, the tea will fall 4ft. × 4ft. but should the coffee be 5ft. × 5ft. then the tea will fall 4ft. × 3½.



[In spite of the difficulty of exemplifying our method, the above diagram will sufficiently explain itself, the ciphers standing for coffee trees and the asterisks for tea.]

Let us take the first case, when the coffee is 6ft. × 5ft. as in the above diagram, that is 6ft. across the line, and 5ft. up. In the first line of coffee run a row of pegs 4ft. apart up the centre of the line. Next run a row of pegs 1ft. to the *right* of the next row of coffee trees and another 1ft. to the *left* of the third row of coffee, and so on *ad infinitum* across the field, one line of coffee having a line of tea down its centre, and the next line having two down each side. The first row of pegs run up the centre of the line of coffee will be 3ft. from the second row of coffee trees, and the second row of pegs 1ft. away from that, to the *right*, will make the distance the rows of pegs are apart, 4ft. the required distance. Again the third row of pegs being 1ft. to the left of the third row of coffee is thus 4ft. from the second row of pegs, the required distance. The above will be of use to many we feel sure.

[The plan of lining for tea, suggested in the above article is a very good one where the coffee lines are 6 feet apart. But a great deal of our coffee is lined 5½, and even 5 feet apart. Where such is the case, I would recommend that the ground *be lined anew*, say 4' by 3' in the case of good land, and 3½' by 3' in the case of poor, or blown land. If this is done, it will give a much more satisfactory field of tea, than if the lining of the tea is made to suit that of the coffee. It is of course rather difficult to re-line for tea, a field of coffee, but it can be done, and the owner will be very thankful he did it, if the time comes when the Coffee has to taken out.—*Practical planter.*]—"Ceylon Times."

COFFEE AND WEEDS.

With reference to his last letter, which will be found on page 683, February *T.A.*, Mr. Kearney sends the following:—

Dear Sir,—Taking a glance from my point of view of your "Ed." note I would desire to be clearly understood in my object that each individual planter in his own interest should try my experiment, the cost being so small R12 per acre.

When general results are placed by small experiments and the point satisfactorily established Government may then help in suppressing "leaf-disease."

I feel sure to counteract the effect of this coffee crop destroyer—will not be deemed an unchristianlike act—nor yet be deemed the setting of the Creator at defiance—contrary to it—by striving to help ourselves we most probably will obtain that help which He may consider us worthy of. I shall report steadily my results.—Yours faithfully, GEO. H. KEARNEY.

Note.—Your p. d. or my penmanship is certainly responsible for a good many bad readings of my communication. I am sending with corrections.

The following are the corrections referred to:—

THE PRICKLY PEAR.

To the Editor of "The Colonies and India."

Sir,—I see by the last issue of *The Colonies and India* that the Colonists of New South Wales are anxious to get rid of what they call a vegetable pest, the prickly pear. To do this is, as is well known, no easy matter, as the more the plants are cut up the greater the number of them there are, polyp-like each piece, even part of a leaf forming a new plant.

In South Africa, particularly in those parts skirting the great Karoo plains, we have many miles of land covered with this troublesome cactus; and when sheep-farming was the only industry in the Colony, to hear that there was a stretch of prickly pear on a farm took greatly from its value, and an immense amount of labour was expended in the endeavour to lessen the evil. I saw various methods tried, and the one that, as far as my experience went, proved the most efficacious was that of building up a substratum of loose bushes or brush-wood (stones did not answer), and then stacking the prickly pear on to this, and in time, not being able to take root, it died. I was travelling one time at the foot of the Sneewberg range, not far from Graaff Reinet, when, in driving through a prickly-pear country, I found here and there a plant singularly affected by some kind of blight, and the farmer, on whose ground this occurred, told me that every plant so affected gradually withered and died. The disease was evidently contagious, for I noticed that where it *touched* the next plant became infected, whereas around an isolated plant the neighbouring ones were in a perfectly healthy condition.

What the disease was, and how it came there, the farmer could not tell me; he has very thankful that it was there, and hoped it might spread, though it seemed to him very slow in doing so. I suggested to him, if that were his wish, to inoculate the healthy plants by placing a leaf from a diseased one in each as far as he was able. He seemed amused by the suggestion, but I heard afterwards that he had tried it with success.

However, at the Cape we have always considered that prickly pears have their uses; in times of severe drought their great succulent leaves were lopped off, and, after having their thorns singed, are given to the cattle and sheep to save them from starvation. Indeed, notwithstanding the fine thorns, great herds of cattle feed among the prickly pears, these yielding moisture and fodder when every green leaf and blade

of grass is gone and every water-hole in the country is dried up. And now that ostrich breeding and feather farming have been added to the industries of the South African Colonies, the prickly pear may be called the staple article of food for these birds; for although lucerne and other green food is largely cultivated for their, use, the supply may—and does—frequently fail from the cause before mentioned, namely, the drought to which this country is unfortunately so subject periodically. My late husband, Mr. Carey-Hobson, an old Colonist of great experience, used to say: "Don't destory all the prickly pears, for the time will come when they will be needed in the land."

I am, &c.,

54 Doughty Street, W. C. M. Carey-Hobson.

CLEANLINESS IN GARDENING.

It is generally admitted that cleanliness is necessary for the health of animals, and it is quite as essential for that of plants, which without it suffer perhaps more quickly than ourselves, for when they get their leaves and bark coated over with dust and dirt the breathing pores and air passages are stopped, and root-action becomes enfeebled and slow. This is no fancy sketch, as many know who have had much to do with gardening, the best cultivators are so fully alive to the importance of keeping plants clean that they are always on the watch to free them from insects, which not only interfere with and cripple their growth by feeding on them, but do even more harm by the excretion they exude, and the way they seal up the pores. Take scale for instance, which confines itself mostly to the bark—or mealy-bug, that lives anywhere or on anything—and what can be more injurious than they? And yet the injury they commit is not so much from what they take from the plant as what they add to it, or in the way they affect it as mentioned above. It will be seen, then how necessary it is to free them from these parasites. Fortunately they succumb readily to paraffin, which is unquestionably one of the safest and best insecticides that can be had, for which proper care in mixing and applying it does not hurt anything, and has the merit of actually improving such foliage as that of the Gardenia or Camellia, to which it seems to impart an additional polish and lustre. For Peaches, Pears, or other fruit trees infested with scale it has no equal, as they may be gone over quickly by the aid of a syringe and wetted all over, and in a short time the scale, which before here able to cleave tightly, will be compelled to leave their hold, as the penetrating power of the paraffin is so great that, invulnerable as their coats seem, it soaks them through and through. The remedy for aphis is well known and easily carried out, and although they may be dealt with in a variety of other ways, such as by the application of tobacco-dust and insecticides used in a liquid state, nothing answers better than fumigating where the smoke can be confined, as it can always be in houses or pits. Thrips, too, are readily vanquished by the fumes of tobacco, but to be thoroughly effectual it is necessary to repeat the dose two or three time in quick succession, which is better than only one strong application, and running the risk of injuring the plants. To get rid of the excreta of insects and other dirty deposits from the foliage, the best way is to syringe it over with warm soapy water, which should be clear and soft, and after this has had time to soak in and soften the dirt, a thorough rinsing from the garden engine will remove it altogether, and make the leaves clean. Camellias always pay well for sponging, and it is a good plan to go over these at this season before the buds are further advanced, and give them a good washing after the engine has been brought to bear on them, as the beauty of the flowers is much enhanced by having bright glossy foliage to back them. Not only is it necessary to have the leaves and bark of all plants perfectly clean if they are to be maintained in health, but it is just as important that their habitations should be made in the same condition, and especially is it so as regards the roof—the glass—for light is life to vegetation, and few plants in houses at this time of year get enough for their welfare. All sashes and woodwork, too, are greatly improved by a good scrubbing, which, if soft-soap and water are used, is almost equal in its beneficial effects to a coat of paint, as it removes all filmy deposits, that harbour and hold the wet and carry decay into the wood. The best time to cleanse glass is when the atmosphere is damp and heavy, as then the vegetable matter with which it is coated becomes slimy, and may be started quickly by using a large soft bursh, followed up with plenty of water. This, driven on with force after the rubbing, will wash all off and make the glass clean, which will then admit the full rays of the sun, so cheering to plants at this season. The plants and glass clean, the next thing is to look to the soil and the pots, the former of which should be gently scraped and surfaced over so as to remove any mossy growth and let in the air, without which roots suffer, and the earth they are in soon becomes stagnant and sour. Dirty green pots are a frequent cause of the latter state of things, and they should therefore be scrubbed outside when in use, and always well washed all over and dried before putting plants in. Where there are walls in houses, a fresh coat of lime wash has a very sweetening effect; and not only this, but it adds to the light and gives a more cheerful appearance. In the sweeping and cleaning of floors the great thing is to avoid dust, which floats about in the atmosphere, from whence it is deposited on the plants and adheres to the foliage.—F. S.—*Gardeners' Chronicle.*

THE BAMBOOS

are thus noted in a paper on Arboriculture in the *Indian Agriculturist*:—To every one in India the name of bamboo is familiar; but every one knows such bamboos only which are found in places where he is located. For instance, in Oudh, there is one variety of bamboos called *kat bansi*, on account of the long spines, known to botanists by the name of *Bambusa Spinosa* of Roxburgh. The bamboo takes up great deal of space, does not grow straight, but from a certain height obliquely and crookedly, crossing other stems, throwing out dense spiny branches, forming impenetrable and formidable bush, which would retard and repel cannon balls (for which quality it used to be planted outside the *gurhs*—forts—to battle and repel the attacks of enemies), by which extraction of the stems become very difficult and expensive, and therefore not profitable. Judging from this bamboo, the people of Oudh would shrug their shoulders on hearing of *bamboo cultivation*, being no doubt ignorant of the large number of species free from thorns, perfectly straight in growth, easy of extraction, strong and durable, and useful in multifarious ways. Bamboo in its humble way is as useful, nay, in some instances more, but far cheaper than timber. In China, Japan, and Burmah, houses are built of bomboos, fancy trays and baskets, richly lacquered work-boat masts, fishing rods, sticks, *morhas* and couches, sericultural apparatus of all kinds, and many other things are made in these places and in India (where available, but in less ingenious fashion). A chief recommendation for the cultivation of bamboo is, that it grows very fast, coming to maturity in 3 to 5 years. In most parts of India the bungalows are made of sun-dried bricks, whitewashed, door and door-posts and windows made of wood, and the rest having bamboo work. When bamboo is not to be found, saplings of *Shorea robusta*, or that of *Acacia arabica* (if available) are used. The bamboo region stretches from the Lower Himalayas to Lower Bengal, the whole of Burmah (British and native), all Siam, China, and Japan, in the continent of Asia. These places have the best bamboo whether for industrial or for decorating purposes: in addition to these, some genera and species highly valuable are also found in South America, parts of Africa situated near the sea, Ceylon and Java, the Phillippine Islands and Madagascar. The bamboo genera are very numerous, and have many species and varieties. I will mention some of them which will grow in the plains of India, where this very useful plant is not to be found, forming artificial bamboo forest.

Bambusa aspera (Poiret).—Native of the Indian Archipelagoes. A lofty bamboo, 120 feet high. The stem is thick and very strong: it is straight in habit of growth, and has no spine. Propagated from off-shoots—or from cuttings.

Bambusa vulgares (Wendland).—The common spineless bamboo of Bengal. It grows very fast, acquiring the height of 40 feet in one growing season (rainy weather). The maximum height hitherto, under no care whatever, observed, is 70 feet. The stem of this bamboo is extensively used in Bengal for building purposes and is the one known to the people of Western Bengal, N.-W. Provinces, and Oudh by the name of *Chaboo bans.*

Bambusa balcooà (Roxb.)—Another bamboo of Bengal, 70 feet high, spineless, strong, durable, easily split and worked into fine slices for manufacturing baskets, mats, &c.

Bambusa Brandisii (Munro).—Native of the Tenasserim division in British Burmah. The stem is 120 feet high, two feet in circumference, hollow, but pretty thick in the pith, strong and durable. It is spineless.

Chusquea lorentziana (Grisebach).—Sub-tropic Argentina in South America is the native habitat of this bamboo. It is not lofty, only 30 feet high, but is solid, very strong and durable, and affords much material for manufacture of many bamboo things; is also excellent for buildings.

THE ACTION OF MANURES ON FRUITS.

Cultivated plants are the inheritors of whatever benefits or may have derived from their predecessors. The thing is disadvantages they obvious enough to those who look on plants from an evolutionist's point of view; and the practical outcome is that, except under special circumstances, or for some special purpose, it is best, in our attempts to improve upon what we have got, to deal with a plant that has been in cultivation for a long time, and so avail onrselves of its stored-up inheritance. It would be a long uphill work to start afresh with the crab or wild pear, for instance, although for the sake of getting a new "break" or more robustness of constitution it may be desirable sometimes to begin again at the beginning, or at least to infuse some less conventionalised blood into our plants, if we may so speak. A curious illustration of the contrast between the wild and the civilised condition is afforded in Professor Goessman's paper on "Mineral Constituents in Plant Growth," in the *Transactions of the Massachusetts Horticultural Society*. The Professor has been experimenting on the difference in chemical composition between vines unmanured and vines manured. In the course of his experiments he analysed the juice of a wild vine *(vitis labrusca)* grown without manure. And the juice of the same vine when treated with manure. At one bound the sugar rose from 8·22 per cent in the wilding without manure, to 13·67 per cent in the same wilding appropriately fed. This shows the advantage of the manure. But now, looking, to the analysis of the cultivated variety *(Concord)*, we find that in its juice, even when unmanured, the sugar amounted to 13·89 per cent, so that the cultivated variety, without manure at all, yielded a larger percentage of sugar than did the wild form with ample manure. The increase of sugar is coincident with a large increase of potash, and a largely diminished proportion of lime. In the case of strawberries the wild unmanured variety contains much less potash, much more lime, much less magnesia, much more iron, and about the same percentage of phosphoric acid as the cultivated and manured variety. The wild strawberry, moreover, contains one part of acid two to of sugar, while in the cultivated varieties the proportion of acid is one to four or more of sugar.—*Indian Agriculturist.*

CINCHONA CULTURE.

We gave, in our last, a very brief notice of Van Gorkom's Handbook on Cinchona Culture, as translated by Mr. B. D. Jackson, of the Linnæan Society, but the work is of so much practical importance to a large section of our readers that no apology will be needed for recurring to it at greater length. The Dutch claim to have successfully introduced the cinchona plant into Java, in 1854, whereas it was not till 1859 that Mr. Clements Markham brought it from Peru to India. Comparatively little progress was, however, made with the cultivation in Java before Hans Van Gorkom took charge of the government garden there, in 1864, and to him really belongs the credit of having successfully established the industry there. He found, upon arrival, that the seedlings imported were chiefly the inferior species of cinchona, *C. Pahudiana* (*C. Ovata*), of which 531,456 were at the end of 1863, under cultivation in the open ground, while the plantation only contained 7,498 calisaya plants. But in 1864 the cultivation of *C. Pahudiana* was restricted and special attention given to the more valuable species of *C. Calisaya*, and the success of the plantations was assured by the planting out in 1866 of 12,000 young Ledger plants that had been raised from seed obtained from Mr. Ledger in 1865. Since 1872 *C. Ledgeriana*, *C. Officinalis* and *C. Succirubra* have been exclusively propagated, with the result that in 1880 the plantations contained 498,000 ledgeriana, 401,000 officinalis, and 278,000 succirubra plants.

Under the head of "Chemical Investigation" we find a short account of the cinchona alkaloids, and the result of Moens' analyses of the three species under cultivation, whence it appears that in 1879—

	Total alkaloids.		Quinine.		Net weight of bark
	min.	max.	min.	max.	in ½ kilos.
Ledgerina gave	6·1	8·1	6·0	7·0	7,850
Officinalis „	5·3	6·8	1·2	4·6	3,365
Succirubra „	6·0	8·0	0·6	0·9	25,201

In 1878 Moens showed by an analysis of the outside scrapings or shavings of Ledgeriana, that the old method of the cascarilleors, which consisted in depriving the thick branches of their epidermis, was a costly operation, for in the samples of shavings he found 9·5 and 7·5 per cent. total alkaloid, containing 8·3 and 6·7 per cent. quinine respectively.

By the scraping process Moens and Scheffer ascertained that a kilogram of superior bark could be obtained annually from each tree; the author considers, moreover, that scraping might be done once or even many times with good results, but skill is required to prevent injury to the tree.

In Java, as it is now found in Ceylon, no variety of chinchona can be cultivated with better prospects of speedy and ample production than the succirubra; but the author is of opinion that so long as quinine is of primary importance, there can be no satisfaction in the exclusive cultivation of the succirubra.

The amount of alkaloids in the bark does not regularly increase with the age of the tree, and in normally developed trees, the maximum amount of alkaloids will be in trees from six to eight years old. The author does not regard the process of renewing under moss to be applicable to inferior kinds of cinchona; as is now well known, its effect on succirubra is to increase the yield of quinine and to decrease the cinchonidine, and on officinalis to suppress in most cases cinchonidine entirely.

In chapter XI. the artificial propagation by cuttings, with a description of Veuleman's method of side grafting Ledgeriana on succirubra stems, which was first carried out in 1879. On this point we read, "For scions young twigs of Ledgeriana trees are taken, those with one joint are large enough, though as there are no reasons for extraordinary economy it is better to use tops of branches with two or three joints. The woody stem of a young succirubra plant serves as a stock, preferably a seedling, because cuttings usually possess a less developed root system. Succirubra stems as thick as a lead pencil offer sufficient surface; stronger stems may perhaps supply more nutriment to the scions, but it is an advantage on the other side that the diameter of stock and scion should agree, that the opposed barks may be united as completely as possible."

The best results are expected from this method, and it has the further advantage of requiring no propagating houses, and of being applicable after cropping an inferior cinchona plantation.—*Planters' Gazette.*

New Products in Lower Haputale, Ceylon (about 1500 Feet above Sea-level).—Cocoas are growing very fast —12 months in the ground, 4 ft. 6 in. to 5 ft. in height. Liberian coffee too is growing very fast before it began to grow, but, once it started, it came away and soon threw out primaries. I am convinced though, that thick shade, even in our hot dry climate, is a mistake. Liberian coffee simply glories in the sun-light, and seems to grow better in dry weather than in wet. I have tried plam nuts, but although those that germinated are alive, that is about all that can be said for them. Ledgers at 1,200 feet above sea level are growing very fast, in fine loamy soil. White ants play great havoc amongst the young cocoas, when first planted out. I have tried chopped aloes, placed round the plants both below and above the surface, and have been very successful in keeping off the enemies The aloe soon rots, especially below the surface in showery weather, and the ants don't like the smell it gives out so keep away. Chopped aloes fermented for a week or ten days will keep any insect away from nurseries, and is also calculated to poison any one who goes too close, too often. I am going to try cardamoms next year. I have found the wild kind in several places about our low jungles. Calisayas too are in our nurseries for future planting. I tried some Nalkanaad coffee, but have a good mind to pull it all up again, as it has been attached most virulently by leaf disease, and the plants worst attacked are those still in

the nursery. When we first planted, about the middle of November last, there were no germs visible. It *may* throw off the attack and not suffer much in the future. —*Cor.* "Ceylon Times."

A Forest Monarch.—Near Mexico Mo., on the farm of Charles Cowan, there was a tree that measured nine feet in diameter at the butt; it was 101 feet high, the first limb putting out 30 feet above the ground. The age of this tree was supposed to be 300 years. When the tree was felled and cut up it made 800 rails, 300 fence posts and 10 cords of wood. By its fall 12 squirrels and one racoon were killed.—*Chicago Lumberman.*

Tree Planting extraordinary.—It may not be generally known that the Duke of Athole is one of the most extensive tree planters in the world There are already vast woods and plantations in Athole and Dunkeld, and as, of course, they exist for use as well as ornament, large numbers of trees have to be planted annually to maintain the woods. Indeed, every year the Duke plants from 600,000 to a million trees. During this season a plantation covering 2,000 acres has been completed. It may be remembered that the Duke of Athole's plantations were thinned of 80,000 trees by the gale which destroyed the Tay Bridge. When the Planter-Duke began operations on a large scale, in 1774, the Dunkeld hills were almost bare. During his life the Duke, who may be described as a true benefactor to his country, planted 27,000,000 trees, covering 15,000 acres.—*Land.*

Gigantic Olive Trees.—A correspondent of the Berlin *Garten Zeitung* states that there is an olive tree at Bendinal, near Palma, in the Island of Majorca, that has a trunk 13 metres in circumfernce. The tree is of little height, and has few branches. Its fruit is like that of the yomger trees. He goes on to say that the olive trees of Jerusalem are computed to be 2,000 years old, and they are only 6 metres in circumference. How old, then, he asks, may the Majorca tree be? Perhaps not so old as those at Jerusalem, we answer. Coutance, in his admirable "History of the Olive," mentions one tree as having a trunk 12½ metres in circumference close to the ground, and 6 metres at 1 metre from the ground. This tree stands between Villefranche and Nice, and was a notable tree in 1515. He also quotes another writer, though he does not seem convinced of his veracity, who describes an olive tree whose hollow trunk was so large that a score of persons could take shelter withiu it at once.—*Gardeners' Chornicle.*

Effect of Trees and Tree Planting on Climate.—The following is an extract from remarks with reference to the influence of woods and forests on climate, made by Dr. Schomburgh in an appendix to his report of the Adelaide Botanic Garden:—"If any one still feels inclined to doubt the influence of forests on the climate of a country, I beg to give several instances of modern times. The Delta of Egypt, well known for its dry climate after the destruction of its forests—olive and other plantations—had about six rainy days every year on an average; but since so many millions of useful trees have again been planted, the rainy days have increased to forty days annually. It is also mentioned that the Viceroy, Mehemet Ali, had planted on the Delta twenty millions of trees. These results are confirmed by renowned travellers in Egypt, but especially by Mons. Pouchet. Many millions of trees have been planted in the barren and swampy districts of France, also thousands of acres in the desert of Algiers have been transformed into forests with trees suitable to the climate, and with surprising results. By the last accounts these plantations, especially of the Australian species, have already reached the height of 30 to 40 feet, and with their rapid growth a great change of the climate is observable, and twice more rain and dew has fallen in the neighbourhood of these forests than before. More than sixteen geographical square miles of the swampy and unhealthy country along the coast of the Bay of Biscay, in the Department of Lands, where swamp fever prevailed, have been planted with millions of trees, especially the cork oak, and swamp pine (*Pinus maritimus*), with a surprisingly beneficial result. Not alone have the trees drained the land, but they have changed it into a healthy country with fine forests."—*Journal of Forestry.*

Cardamoms.—In rich moist lands in Northern Queensland this plaut should be readily established, and prove a valuable addition to our marketable products.—*Queenslander.*

Palm Seeds.—We hear from Mr. Joseph Stevenson, Honorary Secretary, Agri-Horticultural Society's Garden Madras, that he experiences great difficulty in makiug exchanges of Palm seeds. At the present time the garden authorities possess quantities of seeds of the following Palms:—Corypha umbraculifera, Livistona mauritiana, Elæis guineensis, Caryota urens, Areca catechu, and several varieties of Phœnix and would be glad to receive offers in exchange from some of our readers.—*Gardeners' Chronicle.*

Cattle Poisoned by Laburnum.—I have always understood that the seeds of this tree are the part containing matter injurious to both human beings and cattle, and as your correspondent, Dr. Stark, mentions that there were pods both on the Laburnum that proved poisonous, and on the branches that were eaten with impunity, I conclude that the pods on the first contained their seeds, and that those on the branches had shed them, or else that the poison is more active at one particular stage of the ripening process that it is at another. Holon E. Watney..—*Gardeners' Chronicle.*

Wood-Ashes.—The usefulness of wood-ashes as a manure for the garden generally is now fully acknowledged on all hands, and, thanks to the laborious iuvestigations of analytical chemists who have leut their aid to the practical horticulturist, we also know that it is more necessary to some members of the vegetable creation than to others, or, at least, is required in larger proportion in the soil in which they are cultivated. But it does not necessarily follow that the knowledge thus acquired is always turned to the best practical use, or that any more care is now taken to secure every available source of supply suitable for charring for ashes than was done many years ago, before gardeners were able to give any other reason for their practice than that it was justified by results. Mons. J. Ch. Puls, writing on the colouring of Grapes in the *Bulletin d' Arboriculture* for October, says:—"Another cause may, however, prevent good colour in some soils. The Grape that is in this the most sensitive is Mrs. Pince's Black Muscat. It does not colour well when potash is deficient in the soil, therefore I recommend always to cultivate one cane at least in a house of Muscats, because it will inform you of the state of the border." And he concludes by recommending the employment of wood-ashes in order to supply the deficiency of potash. Chemical analyses have shown what a large percentage of potash is contained in the berry of the Grape, and whether or not M. Puls be correct in directly attributing the lack of colour in the variety Mrs. Pince to a deficient supply of that essential in the soil, there can be no difficulty about acknowledging that the peculiar inherent weakness of any variety may be expected to develope itself whenever the conditions under which the plant is cultivated are in some particular unfavourable. Thus, indirectly at least, more ills than we are perhaps at present prepared to acknowledge owe their origin to the lack, or it may be superabundance, of something in the soil. A better time than the present for directing attention to the necessity for making the best practical use of our acquaitance with the value of wood ashes, cannot be expected to occur for some time. There are at the present time many thousands of tons of branches of trees torn down by the gale of last month throughout the country, which would make most valuable supplies of ashes that would have a magical effect on gardens requiring just that assistance. Quantities of the *débris* will litter the ground in parks, fields, and lanes for a long time, or be summarily burnt in small heaps in order to clear it away, and the resulting ashes lost for all practical purposes, if not systematically collected and carefully burnt. To secure in the fullest degree the retention of highly beneficial gases given off during combustion the fire should be kept well smothered with any small refuse that can be obtained. Earth thrown upon a covering of the smaller twigs will have the desired effect, but will considerably increase the bulk of the residue; this will, however, be but a slight disadvantage, quite disproportionate to the saving of useful manure obtained by the retention of the carbon, &c., which would be carried off in the atmosphere were not the mode of combustion regulated. Ralph Crossling.—*Gardeners' Chronicle.*

A CEYLON PLANTER IN QUEENSLAND.

Brisbane, Jany. 8th, 1882.

There can be no doubt about Queensland being a fine country and better than other colonies as regards tropical agriculture; for anything will grow and thrive here, and although Brisbane is out of the tropics, the few coffee trees in the garden here are very fine, and the crop on them now ripe would make a good many in Ceylon look pleasant at such a crop. I have seen this patch of coffee now since the end of February, when it was covered with blossom, and, when it set, you would have put it down at 15 cwt. or at that rate per acre; but a short time afterwards a lot of it went off with something like white bug. I am sure that now ripe there is quite 8 cwts. to be picked. Brisbane, however, is too far south for coffee. At "Mackay" some 500 miles north from this, there is a small field of very fine coffee owned by a German, but they know nothing about it, either how to cure the crop or prune, or anything else. I did not see it, but two Ceylon men were at Maekay before they came here and told me about it. One F—— from Maturata went on to Fiji, the other R—— went back to Maekay in May to take up land on his own account. There is no leaf-disease on the coffee here or any sign of it, and as soon as the difficulty about coolies is got over, this field of coffee would be a good speck for seed, and I believe could be got cheap. Northern Queensland is bound to be a coffee country before long. I was prepared to go in for it, as I understand there is a lot of rough land suitable for coffee and cinchona, and not suitable for sugar-cane.

The first they have heard about cinehona was only a few months ago. A——, that was on ——wood sent over 1 lb. of officinalis seed to the *Courier* office, and a good many have been asking me about it. I have no doubt there will be a good opening in the North for both coffee and cinchona, though there will no doubt be a good many difficulties to contend against. Labour is the principal one. The law of the country makes it free to any one to bring coolies at their own expense, at present, but that would be the difficult part of it. As soon as the new law about coolies is passed, assistance will be got, and the B. I. steamer Company are about to start another line of coast steamers to start from Calcutta, calling at Madras and Colombo, and all the ports down the Queensland coast, and as far as Sydney. This will give a chance of bringing coolies at a cheaper rate. "Rama Samy," I have little doubt, would like the country well enough as the climate would suit. It is not so wet as Ceylon; he could grow everything; get a cheap cow or a sheep; but cocoanuts would have to be got for him and rice. At the price of land, gardens could be easily given him, paddy grows well, but it wants some one to cultivate it; a white labourer would not care to puddle a paddy field. The "Kanakas," South Sea Islanders, at present employed on the sugar estates are fair workers but you would not like the ugly brutes after the coolies.

The new bill about the regulations with the Indian Government for the importation of coolies is expected to be settled this session; only the labouring class here are very much against coolies coming here. A start has, however, been made, I hear. 25 Singhalese came in the *Scotland* for Normanton on the West Coast of Queensland at the Gulf of Carpentaria. The first thing to be done however, is to select land. The largest select on one man can take up is 1,280 acres, but had one the money he could take up some for each of his sons. Any number can do this or take up half that amount for each, paying 2s. per acre for ten years when the land is your own, provided the conditions are fulfilled; that is, you have to spend an equal amount on improving the land, buildings, &c. In consequence, I see accounts of people getting old men from poor-houses to take land out in their name and having it all transferred before the old chaps die; and then they hold the lot at the end of ten years. Land can be opened very easily by growing sugar on the flat land and selling the cane till you can put up machinery. You get a return from sugar in 12 or 15 months from the time you commence that will double the outlay. I know a man here who cleared 12 acres and, in the above length of time, cleared all he had then paid out for survey and rent on the whole selection. About opening I believe Chinamen can be got to clear the land by contract, at about Ceylon rates, and on scrub land you can get a contractor with a team of bullocks to plough it up twice for about the same rate, £2 to £2 10s. an acre. Cane cuttings for planting are not very expensive. I have not got the books beside me now, as, I had to return them, but the figures are, as near as I can remember,—the return from the first crop of sugar up North is about two tons to the acre, worth at the ship's side from £25 to £30 per ton, and sometimes as much as £32. Selling cane realizes only about half and at 10s. and 12s. a ton comes to about half the price of the sugar; but in the meantime on the rough land coffee and cinchona would be coming on.

The figures I have from an estate on the Mary River just about the Tropical line and considerably further south than Mackay. From this estate 14,000 acres were planted; the cuttings of 525 acres of cane, crushed, gave 756 tons of sugar, 62,063 gallons of molasses, 4,257 gallons of rum, 32 overproof. The average yield at Mackay is one ton 8¾ cwts. of sugar alone. This leaves a profit, without rum, &c., of from £5 to £8 an acre. Something can also be made out of the untouched land by feneing and putting on cattle and horses, to find there own living as they require nothing. You can have your own beef, mutton, and poultry as stock of all kinds do well, so that one has only to buy flour, tea, sugar, &c. Stock for this would cost very little—store cattle about £2 to £2 10s.; horses depend on the class, but ordinary haeks don't cost much.—"Ceylon Times."

COLLECTION AND STORAGE OF SEED.

Collection.—Seeds may be obtained either by collecting directly, or through contractors, or by purchase in the market, or by exchange. Owing to the backwardness of forest culture in India, the third source scarcely exists for us, and the fourth is almost as limited. This is, however, no great disadvantage, as seeds collected directly or through contractors must necessarily belong to the latest crop, and are more likely to be fertile and sounder than those obtained otherwise and not only this, but they can be more thoroughly tested. The best seeds are produced by full fertile, healthy, vigorous trees growing not too close together in a favorable soil and situation. Very young trees usually furnish a large proportion of barren seed, while very old or weakly trees yield seeds which are not only difficult to keep but also produce weak plants. Deformities in trees are often inherited, as for instance twisted fibre, a squat habit, &c. Twisted fibre can be easily detected in trees possessing a cracked bark or rhytidome, as the cracks follow the twist.

Seeds ought to be collected only when they are completely ripe; such as are not fully ripe when taken off the tree do not possess the germinative faculty in the same degree as ripe seeds and, moreover, lose that faculty much sooner. The ripe fruit of some species persist on the trees for a more or less considerable time; *e.g.*, of teak, *Terminalia tomentosa*, *Pterocarpus Marsupium*, sissoo, &c. Such fruit one need be in no hurry to harvest. But there are other species, the majority of the seeds of which, with or without the rest of the fruit, are shed as soon as, or soon after, this ripens; *e.g.*, sal, deodar, *Quercus semecarpifolia* and *dilatata*, *Abies Webbiana*, birch *Lagerstræmia parviflora*, *Schrebera swietenioides*, &c. The collection of such seeds evidently admits of no delay. Rainy weather ought, whenever possible, to be avoided for the collection of seed especially of such as are small, *viz.*, of *Anogeissus*, birch, *Adina cordifolia*, *Stephegyne parvifolia*, &c.; but this prohibition obviously does not extend to such seeds as are to be sown at once, or, which comes to the same thing, as cannot under any circumstances be preserved, *e. g.*, sal, *Quercus semecarpifolia*, &c.

According to the various species, seeds must be collected in different ways. The fruit may (i.) be hand-plucked off standing trees, or (ii.) off felled trees, or (iii.) be gathered off the ground after they have fallen naturally, or lastly (iv.) be broken off with a hook from standing trees.

(i.) Hand-plucking off standing trees.—This method is the most costly of the four, but is the only one applicable in the case of small or light fruit, *e. g.*, *Pterocarpus Marsupium*, *Ougeinia dalbergioides*, *Anogeissus*, khair, sissoo,

Hardwickia, elms, maples, ash, &c., or of small light seeds that escape from the ripe fruit still hanging on the tree, *e. g.* deodar, silver fir, birch, *Schrebera swietenioides*, *Andromeda*, &c. The seed collector must climb up into the crown of the tree, with or without the help of a ladder, just as he can manage, and with a sack slung over his shoulder. What he cannot reach directly with his hand, he must draw to within arm's length of himself by means of a hook attached to the end of a light but strong sapling or bamboo of sufficient length. Branches and branchlets break off less easily when drawn upwards than if pulled downwards; hence it is always advisable for the collector to climb up to the highest point he can attain and begin by plucking off the fruit hanging at the summit of the tree. The fruit of many species is more or less articulated to the twig which bears them, and is thus easily gathered; but that of some species can only be plucked by twisting or otherwise forcibly breaking off the twig. For the latter class of fruit the use of a cutting implement, such cas a pruning knife is to be recommended.

(ii.) HAND PLUCKING OFF FELLED TREES.—Trees that are to be cut for export in the ordinary course of work often yield a considerable supply of good seed. They should be felled immediately the fruit is ripe. A pruning hook often facilitates very materially the collection of fruit. This is the only method applicable to the various kinds of bamboos.

(iii.) GATHERING OFF THE GROUND.—The seeds that fall first are generally barren or worm-eaten; they should invariably be rejected. To this end the dead leaves and early fallen fruit or seed should be swept away from under the selected trees. This method of collection is very economical, and is peculiarly suited to large heavy fruit which falls more or less perpendicularly and which does not break up and allow the included seed or seeds to diperse, *e. g. Quercus incana*, the sandalwood tree, &c., sal, *Terminalia Chebula* and *belerica*, &c. To help the fall of the seed or fruit, the branches of the trees may be shaken.

(iv.) BREAKING OFF THE FRUIT FORCIBLY FROM STANDING TREES.—When trees marked to fall within a year or so are chosen as the seed-bearers, it may be found inconvenient or impossible to fell the trees as soon as the fruit ripens. On account of the nature and small size of the fruit and seed, the Third Method may also be inapplicable, while the First would be unnecessarily expensive, since there is no reason for sparing the fruit-bearing branchlets and twigs of such trees. The fruit may then be broken off singly or in bunches with the aid of a strong hook forming a sharp angle of about 30° firmly attached to one end of a long sapling or bamboo. The inside edge of the hook should be sharp and serrated and slightly curved inwards. The hook should be passed over the fruit-bearing branchlet or twig at the point at which it is to be broken off, and jerked downwards; or, if that does not suffice, it should be twisted round once or twice, by which means the branchlet or twig, as the case may be, will be firmly caught in it and a single jerk will then suffice to cut the former through. Where small wood has no value, and there is no objection to thinning out the crowns of the trees branchlets of a certain thickness may be cut off with a bill hook, and the fruit then hand plucked from them. Some trees produce bunches of fruit, the common stalk of which dries up at maturity and easily disarticulates from the rest of the branchlet. The panicled fructification of teak is a good instance in point. The present method may be employed with such trees, both independently and also to supplement the Third Method, when all the fruit, although they ripen more or less simultaneously, do not fall together.

TREATMENT AFTER COLLECTION.—The fruit of many trees require to undergo some previous manipulation before the seed is in a fit condition to be sown or stored up. Either (a) the seed is enclosed in a fleshy pulp, *e. g. Dillenia*, *Schleichera trijuga*, *Artocarpus*, *Gmelina arborea*, *Diospyros*, &c.; or (b) it is covered with a thick tough fibrous rind, *e.g.* cocoanut, &c.; or (c) it is included in a capsule or pod, or between scales, *e. g. Lagestræmia*, *Schrebera*, *Michelia*, khair, *Hardwickia*, babul, *Coniferæ*, &c., or (d) it is surrounded or armed with foliaceous or comaceous appendages, which interfere with its uniform ditribution in sounding as well uselessly increase its bulk and weight, *e.g.* Teak, some *Terminalias*, *Pterocarpues Marsupium*, elms, maples, pines, firs, poplars, willows, &c.; or (e) it is so full of moisture that it cannot be stored up at once without heating and fermenting, *e.g.* pines and firs, *Anogesssus*, *Quercus incana*, &c.; or (f), although as ripe as it can ever become on the parent trees, it would germinate badly or after much delay if sown as soon as collected, *e.g.*, teak, *Terminalia tomentosa* and *Arjuna*, *Pterocarpus Marsupium*, babul, ash, &c.

(a). SEEDS ENCLOSED IN A FLESHY PULP.—In many cases the pulp may be got rid of by allowing it to rot in heaps, and then washing it off in large vats with abundance of of water, working the contents of the vats well with strong rods bound together broom-fashion. Edible fruit, such as that of *Zizyphus*, *Diospyros*, *Buchanania*, *Schleichera* &c., give no trouble; people who live in or close to the forest will bring in all the seed required in return merely for the privilege of collecting the fruit with occasionally a trifling money renumeration added. Some kinds of fruit may also be given to goats and cattle, which eject the seed when chewing the cud, *e.g. Zizyphus*, *Terminalia belerica* and *Chebula*, *Phyllanthus Emblica*, *Gmelina arborea*, *Prosopis spicigera*, &c.

(b). SEEDS COVERED WITH A THICK FIBROUS RIND.—The rind must be torn off with the aid of force and special shears.

(c). SEEDS INCLUDED IN A CAPSULE OR POD, OR BETWEEN SCALES.—The quickest method, when that is practicable, is the application of heat, under the action of which the valves of the capsules or pods and the scales of the cones open out or disarticulate, and allow the enclosed seeds to escape out. In many cases simple exposure to the sun suffices; in others, however, a higher and more sustained temperature is required, and then special drying houses are necessary, in which the fruit to be treated is exposed to the direct action of air heated by steam pipes or over an open fire, and kept at the required temperature with the aid of thermometers. The coverings and scales are separated from the seed by raking or riddling or winnowing, according to circumstances. But the application of heat does not suffice for, or even does not succeed at all, with the fruit of many species, *e. g.* sissoo, *Hardwickia*, babul, khair, &c. In this case, if the seed is tough enough threshing in sacs or in the open air, or treading with bullocks on a well-beaten level floor in the manner of the Indian agriculturist gives good results. Some of these seeds, however, chiefly of leguminous plants, do not stand such rough treatment, *viz.*, *Hardwickia binata*, sissoo, &c., and the only way to free them, as far as I know, is to manipulate each fruit individually with the hand, in case the separation of the seed from its covering is deemed necessary.

(d). SEEDS WITH FOLIACEOUS OR COMACEOUS APPENDAGES.—The whole sale removal of these appendages, except one by one withthe hand, is not always possible without injury to the germinative power of the seeds; but whenever practicable, it should be effected. If the seed is hard or tough, friction, more or less rough, suffices to detach these appendages. When this is the case, a very expeditious method is to nearly, but non quite, fill large stout sacs with the seed, and to thresh these or work them violently backwards and forwards, according to the toughness of the seed, until the appendages are detached or crushed, when they can be easily separated by the ordinary process of winnowing. Treading with cattle may sometimes be found efficacious. Threshing is necessary for seeds of *Terminalia tomentosa* and *Arjuna*, *Pterocarpus Marsupium*, &c. Treading with cattle or friction in sacs will succeed perfectly with teak, &c. With brittle or otherwise delicate seeds the following process may often be employed with the best result:—They should be spread out and sprinkled over lightly with water from a pot with a fine rose, and moistened thus, they should be collected into large heaps. As soon as a gentle heat is felt on inserting the hand into these heaps, they ought to be spread out to dry. When the seeds are again dry, the appendages will be found to have disarticulated of themselves.

(e). SEEDS TOO MOIST TO BE STORED UP AT ONCE.—The seeds of many species have to be plucked from the parent tree before they are quite dry, in order to prevent their being disseminated and scattered far and wide. Other kinds of seed contain a great deal of moisture even when they fall off naturally. Such seeds should be

spread out not more than from 2 to 3 inches high in high in a dry, airy, sunny place, and turned over with a rake twice or thrice daily for a period varying with the kind of seed and the dryness and temperature of the weather. After this they should be piled up higher, the raking being continued as before but being limited to only once a day. This latter process should go on until the seeds are sufficiently dry. Experience alone can tell when this is the case. It is needless to say that in the cold weather the seeds should be removed under shelter while dew is being deposited. As regards seeds that are moist even when they are shed naturally, this drying is really the completion of ripening process, for such seeds germinate more promptly when they have been thus dried than if sown as soon as they fall off from the parent tree.

(f). Seeds that require a further process of ripening after falling off from the parent tree.—Among agricultural crops our gram is a well-known instance of such seeds. It will germinate freely only several months after it has been harvested. Instances of forest seeds, already given higher up, are those of teak in Central India and Bombay, of *Terminalia tomentosa* and *Arjuna*, of *Pterocarpus Marsupium*, babul, ash, &c. Drying increases the germinative facultly of each one of these species, especially the power of swelling up of the embryo and of the perisperm (when there is one) by the imbibition of water. In the case of teak in Central India, it would appear that continued exposure to all the alternations of the weather during a whole year, provided fermentation is prevented, favours the second ripening process.

—*Indian Forester.* E. E. Fernandez.

CINCHONA LEDGERIANA A DISTINCT SPECIES.

So far back as September 1881, Dr. Trimen sent and interesting paper on this subject to the "Journal of Botany" (it was published in the number for November following) giving a full description of the new species, the same being accompanied by coloured plates shewing the leaf, flower buds, calyx, &c. Through an oversight, we failed to reproduce this valuable contribution to Cinchona literature at the time a copy reached us, but we are now reprinting the letter press for the April number of the *Tropical Agriculturist*, and in doing so, we are able to give at the same time a curious paper from the same journal (number for January 1883) by Dr. Kuntze endeavouring to controvert Dr. Trimen's argument and to demonstrate that Ledgeriana is a hybrid. Dr. Kuntze in a previous monograph of cinchona endeavoured to make out that there were only four species :—Weddelliana (including Calisaya) ; Pavoniana (including Micrantha) ; Howardiana (including Succirubra) ; and Pahudiana. All other cinchonas he regards as synonyms or hybrids of these four species ; but Dr. Kuntze has failed to convince scientific botanists of the correctness of his views. In fact many of his notions are rather laughed at, than gravely regarded. Dr. Kuntze is a very eccentric and speculative botanist, and his views on cinchona, hastily adopted on imperfect data, are generally allowed to have little weight. It is perhaps desirable that he should have an opportunity of still advocating them in a scientific periodical, but it is as well for the public to understand that they have not been accepted by any other botanist acquainted with cinchona in the East. It was on this account doubtless that Dr. Trimen did not refer to Dr. Kuntze's views of the origin of *C. Ledgeriana* in the short article towhich he refers, for Dr. Trimen must be well acquainted with his book on *Cinchona*, having reviewed it on its appearance in 1878, and he also has alluded to it in his "Medicinal Plants" under "Cinchona," and again in Mr. T.C. Owen's Manual (p. 19). —Dr. Trimen has now, we understand, sent a brief reply to Dr. Kuntze's statements in the latter's paper in the December number of the "Journal of Botany," and has been enabled to show that Mr. Gammie, in answer to enquiries, denies absolutely having made any such statement as Dr. Kuntze credits him with (that Ledgeriana originated spontaneously in a Calisaya field and never came true from seed), and Mr. Gammie thinks Dr. Kuntze must have some other kind than *Ledgeriana* in his mind's eye.

By Henry Trimen, M.B., F.L.S.

(*From the "Journal of Botany," Nov. 2, 1881.*)

All who have followed the progress of the great and wonderfully successful experiment carried out in the East during the last twenty years, will be aware how prominent a part as a quinine-yielding tree is now filled by the plant known under the name of *Cinchona Ledgeriana*. The discovery of its value in 1872 gave new life to the flagging Cinchona enterprise in Java, which has since, under the able guidance of the present director, Mr. Moens, taken so leading a position; and the cultivation, propagation, and improvement of this species are now the principal objects of the plantations of the Dutch Government. In our own plantations in Sikkim, after years of neglect as one of the troublesome and hopelessly variable forms of *C. Calisaya*, the plant is now the object of careful cultivation; whilst in Southern India and Ceylon private planting enterprise especially has not been slow to turn to account the knowledge acquired, and the spread of *C. Ledgeriana*, in plantations in suitable localities, is merely a question of time.

There is no occasion to go into details as to the history of this species, but it is necessary to mention that the tree is only known to botanists in a cultivated state. All existing plants in the East are descendants of seed collected from about fifty trees growing on the almost inaccessible banks of the Rio Mamore in Bolivia, in June, 1865. It does not appear that any European has been within a hundred miles of this locality, or that the trees have been again seen. The actual collector was a half-caste, or native servant of Mr. C. Ledger, named Manuel Incra Mamani, who was afterwards murdered.* Mr. Ledger's seed was sent to London, and after being (unfortunately as it has turned out) declined by the India Office, was purchased by the Dutch Government in Dec., 1865, and sent to Java, where it was raised and the plants carefully attended to under the care of Van Gorkom, then director of the plantations. A portion, however, of the same seed was acquired by Mr. Money, a planter in the Nilgiris, whence some found its way to the Government plantations at Ootacamund, and a small quantity to those at Darjeeling. Hence it resulted that plants of this valuable kind were being grown both in India and Java, but it was in the latter country that its superiority as a quinine-yielding variety was discovered.

In Java, too, it was soon observed that though showing a good deal of variation, the plants possessed some well-marked characters, and the name "*Ledgeriana*" became used (first in 1873?) in official reports and as a plantation name, to distinguish it from other varieties of *C. Calisaya*.† In India, however, it was not distinguished from other yellow bark trees, and it is only in the last few years that the trees have been picked out and identified by their botanical characteristics. Seed from Indian *Ledgeriana* also found its way to a few planters in Ceylon under the name of *C. Calisaya*; and trees five or six years old have been found on several estates mingled with other varieties, and generally unrecognized until the characters were pointed out by Mr. Moens during a visit to the island in Sept., 1880.

The name *Ledgeriana* received scientific sanction in 1876, being then published in Howard's magnificent work as *C. Calisaya*, var. *Ledgeriana*, How.‡ In this book, which I regret I have not at present at hand, much information will be found with reference to the plant and its allies. In now publishing it as a separate species, I almost feel to owe an apology for adding another to the already far too numerous

* J. E. Howard in Pharm. Journ., March 13th, 1880.

† Howard, Quinol. Ind. Plant. p. 84.

‡ It is used in Howard's Notes on *Cinchona* in Journ. Linn. Soc. xiv. p. 174 (1874).

specific names in the genus, and I should have abstained from doing so on my own judgment alone. But several supporting facts have been observed, especially by Mr. Moens in his long and intimate acquaintance with, and close study of, the plant and its allies. His opportunities for arriving at a correct conclusion are so much greater than those of any other person, that I feel there is little risk in adopting the view he holds (which will be more fully exhibited in his forthcoming book on the genus *Cinchona*), agreeing as it does with my own less well-grounded opinion.

A point which early struck me as noteworthy was, that among the amazing variety in the progeny of the ordinary *Calisaya*-forms nothing quite agreeing with *C. Ledgeriana* was ever observed. Desirous to know whether this was the case elsewhere, I made inquiries of Mr. Moens, who assured me that he never saw "anything like *Ledgeriana*, either botanically or chemically," to come from seed of a *Calisaya*. I understand that Mr. Gammie has the same experience. This is very remarkable, for the progeny that come from any sowing of *C. Calisaya* seed are certainly less like one another than some are like *C. Ledgeriana*; moreover, seed from the latter has not hitherto been found to come very true, even the progeny of the original seed from Bolivia showing a good deal of variation. But as seen under cultivation this has as yet been always the case with Cinchonas. How far it results from a strong natural tendency to variation, and how much is due to cross-fertilization, we have at present little direct evidence to show. The latter must, however, be a cause, and alone explains the undoubted improvement in the true-ness of seed from a tree hitherto grown in proximity to other species after isolation by their destruction. This has been conspicuously shown in the case of *C. Ledgeriana* itself in Sikkim, the seedlings from which, since Mr. Gammie uprooted nearly all the neighbouring trees, now come remarkably true, whereas before that was done the sporting was so great that Dr. King would not propagate by seed at all. The same results have been even more marked in Java. We may hope for some direct evidence on the subject, however, in time, as Mr. Moens is now conducting experiments in artificial hybridization with a view to comparison of the results with the naturally-produced sports.

So much interest attaches to this *Cinchona* that, though it has been comparatively recently the subject of three fine plates in Howard's sumptuous volume,§ I have thought that a less ambitious figure, carefully drawn from living specimens of the plant cultivated in Ceylon, might fitly accompany this notice. The artist has not been very fortunate in the specimen he had for delineation, which was from a tree grown in poor soil and an unsuitable situation, and flowering at an earlier age than would be the case with a more healthy subject. But there was then little choice as to specimens in Ceylon, where we have but few adult trees of the kind.

The following description gives those characters only which are helpful to distinguish *C. Ledgeriana* from its allies. They are chiefly taken from fresh Ceylon examples, but I have been assisted by dried specimens of some of the original trees from Java, for which I am indebted to Mr. Moens:—

Cinchona Ledgeriana, Moens, MSS.

C. Calisaya, Wedd., var. *Ledgeriana*, Howard, Quinol. Ind. Plant., p. 84, tt. 4—6 (1876).

Leaves when adult varying from pure lanceolate¶ to oval or to linear-lanceolate, or to oblong-oval, *but always having the broadest part at or about the middle* and equally narrowing towards either end, apex sub-acute (rarely acute) or sub-obtuse, base much attenuate into the short petiole, always perfectly glabrous on both surfaces, subcoriaceous, often wavy, full deep green, paler beneath, shining but not polished above, the base of the midrib and petiole more or less stained with orange-pink, the veins prominent beneath, scrobicules not conspicuous mostly confined to the upper vein-angles, stipules enclosing the terminal bud, quickly caducous, lanceolate-oblong, subacute, glabrous, keeled, and with numerous parallel veinlets.

Flowers *small*, on short curved pedicels and thus *drooping or divaricate*, tufted or crowded at the ends of the branches of the usually small rather dense pyramidal panicle; *buds* oblong-ovoid, blunt, when mature *not at all or very slightly widened at the end and never abruptly enlarged there.*

Corolla with a short wide *tube* about 1-6th inch long, *somewhat inflated in the middle*, pale green, *lobes pure white* or somewhat cream-coloured (very rarely pinkish), the marginal hairs copious and long.

Capsule short, ovoid-oblong, rarely more than ⅝ inch and never more than ½ inch in length, capped by the persistent cup-shaped calyx-limb with erect teeth.

As with other species of *Cinchona* in cultivation there is in this a great deal of variability in the form of the leaf, even in adult trees. On the flowering branches they are often narrow and almost strap-shaped, whilst in some plants they are as broad as *C. officinalis*, var. *Condaminea*, from which it is indeed not always easy to distinguish them. The amount of red coloration in the veins is variable, and rarely quite absent. Though always absolutely glabrous when mature, this is by no means the case with young plants; seedlings up to a year or two old are frequently more or less hairy beneath, but as the trees get older this disappears. These young leaves are also often of very large size, and the upper surface usually has a velvety sheen or *reflet*; not unfrequently the under side is of a fine purplish tint; but none of these points are, I think, of much importance. The unexpanded leaves and the buds and young soft shoots have, however, a bronzed or olive-orange tint by which in a field of *C. Calisaya* the plants of *C. Ledgeriana* may often be picked out at first sight. When withering the leaves turn orange-lake to brown.

The tree does not apparently attain any great height; it is distinctly pyramidal in shape, and less handsome in appearance than some other species. The bark is usually rather clean and smooth; but there seems to be considerable variability in appearance, and I cannot learn that any guide as to quality is afforded by it.

The long-styled and short-styled forms seem to be pretty equally distributed in Ceylon specimens, perhaps the short-styled (with exserted stamens) being rather more frequent. I do not observe any correlated differences in foliage or inflorescence. The trees flower here during the months from May to September.

The capsules are described by Dr. King as "nearly globular," but I have seen none of that form, all being as above described. Those originally collected were considered by Mr. Howard to be similar to *C. Calisaya* var. *microcarpa*, Wedd. (figured in the Quinology, t. 15).

The best marks distinguishing *C. Ledgeriana* from all forms of *C. Calisaya* are found in the flowers. Their drooping habit, and more especially the small size, short inflated tube, and white colour of their corolla, are quite characteristic; the difference is well seen just before expansion, when in *C. Calisaya* the tube is topped by a suddenly-inflated knob quite absent in the present species. The flowers certainly thus make an approach to *C. micrantha*, R. & P., but the very different foliage and capsules widely separate the two species. The plant alluded to by Mr. Howard in this Journal‖ under the name of the "Morada," and collected by Pedro Rada on the rivers Bossi and Beni in Eastern Bolivia, is, to judge from the coloured figure given of the young leaves, extremely like *C. Ledgeriana*. The bark, too, is known to be a good sort of *Calisaya* bark. The trees, however, are said to reach a height of 120-150 feet, and the flowers of this "morada" to be "purple"; but a closely-allied form, "la verde," has them "white."

For the specimens figured I am indebted to Mr. Walter Agar. They are from Mahanilla Estate, in the Maskeliya district of Ceylon, about 5½ years old from seed, and about 9½ feet high (being, as above mentioned, grown in unfavourable circumstances). The seed came from the late Mr. MacIvor, Superintendent of the Cinchona plantation in the Nilgiris, obtained, there can be no doubt, from trees which originated from Mr. Ledger's seed.

Peradeniya, Ceylon, September 1st, 1881.

§ Quinol. Ind. Plant., tt. 4. 5. 6.

¶ The sense in which I have always used the terms "lanceolate" and "oval" is that given in English text-books, and more precisely defined in this Journal, 1871, p. 370. But several descriptive botanists use the term "lanceolate" to express a form which I am accustomed to call ovate-lanceolate or narrowly ovate, *i. e.*, with the broadest diameter below the middle; whilst "oval" is employed with extreme laxity for several very different outlines.

CINCHONA LEDGERIANA: A HYBRID?

By Otto Kuntze, Ph. D.

(From the "Journal of Botany British and Foreign" for January 1883, pages 5 to 8.)

Dr. Henry Trimen published in this journal for 1881 (pp. 321-325) a paper entitled "Cinchona Ledgeriana, a Distinct Species," wherein he maintains that C. Ledgeriana is not a variety of C. Calisaya, as Mr. J. E. Howard had supposed. He cites the following marks in support of his position:—(1) The leaves of C. Ledgeriana have always the broadest part at or about the middle. (2) The flowers approach those of C. Micrantha in their drooping habit, small size, short inflated tube, white colour, and also (3) by their buds, which are not at all or very slightly widened at the end, and never abruptly enlarged there, as they are in C. Calisaya. This last character is new to me.

C. Calisaya and C. Micrantha are the only species mentioned as nearly allied to C. Ledgeriana. I have described indeed C. ledgeriana as a hybrid of these two species in my monograph of cinchona* wherein I acknowledge only four species:—Weddelliana=C. Calisaya *pro parte*; C. Pavoniana=C. Micrantha p. p.; C. Howardiana=C. succirubra p. p.; and C. Pahudiana How. All other cinchonas I regard as synonyms or hybrids of those four species. The hybridization of cinchonas has been proved (1) by some direct artificial production of several hybrids, (2) by the fact that the seeds of marked trees produced plants with the mixed characters of another species. There cannot be any doubt as to the copious hybridization of cinchonas; and it is well known that the hybrids in the cinchona plantations have plenty of good fertile seeds; only C. ledgeriana shows an exception, and its more or less great sterility has been often noticed.

Cinchona Ledgeriana originated spontaneously in the Government plantations of Mungpo in Sikkim, as published by me in my monograph of cinchona. Dr. Trimen did not know this fact, and it would seem that he has not read my monograph; for he writes (p. 322):—"I made inquiries of Mr. Mocns, who assured me that he never saw anything like ledgeriana to come from seed of a calisaya. I understand that Mr. Gammie has the same experience." During my visit to Java I never observed spontaneous C. Ledgeriana, but in Mungpo-Sikkim Mr. Gammie and the late Mr. Biermann assured me that "C. Ledgeriana had originated spontaneously there in the calisaya field." Besides Dr. Trimen supports this statement, saying "in our own plantations in Sikkim, after years of neglect as one of the troublesome and hopelessly variable forms of C. calisaya, the plant (C. Ledgeriana) is now the object of careful cultivation." Dr. Trimen is therefore in error to write that "all existing plants in the East are descendants of seeds collected in Bolvia, in June 1865."

But the testimony of the cinchona cultivators—valuable as it may be—is not necessary, for we know a fact that proves the hybrid origin of C. ledgeriana in Mungpo: the imported cinchonas in Mungpo are trees, with the exception of C. calisaya, and all descendants of C. calisaya are shrubs, pure calisaya are small shrubs, and the hybridized calisaya are very large shrubs, because the other hybridizing cinchonas are only trees. C. Ledgeriana of Mungpo is also a large shrub; it became only more tree-like by the art of the cultivators, who prefer trees for bark collecting. When I visited Mungpo, C. Ledgeriana was mostly not yet tree-like. In contrast to this shrubby Ledgeriana of Mungpo the descendants of Bolivian Ledgeriana in Java and Southern India, perhaps also in private Sikkim plantations, are veritable trees. I do not know if there has been imported Bolivian ledgeriana into the Mungpo Government plantations after 1875; but until that date no Bolivian ledgeriana existed there.

The Mungpo ledgeriana shows another individual mark, by which I can easily distinguish it from Bolivian ledgeriana: the former has very divaricate panicles with slender ramification, the Bolivian descendants have a more dense panicle with thicker or shorter branches. The C. micrantha of Mungpo has accidentally such slender divaricate panicles, and all its hybrids at Mungpo, as well as C. ledgeriana, show that individual mark. The Mungpo calisaya field is of very great extension, and it is the same plan on which the former intendant of that plantation, Mr. C. B. Clarke, sowed the calisaya. Mr. Clarke said in November 1875, to me, "we sowed calisaya and got other plants," and among these other plants were many shrubs of C. ledgeriana.

I am anxious to correct the erroneous point of Dr. Trimen's publication, because Dr. A. Garcke† has briefly quoted the paper of Dr. Trimen against my deduction of the hybrid origin of C. ledgeriana; he says also:—"Messrs. Moens and Trimen prove that C. ledgeriana bears fruits like all other cinchonas, and they consider it therefore as a distinct species." As all other artificial and spontaneous cinchona hybrids ripen good seeds plentifully, the fertility only would be no proof for the establishment of a species; besides, the fertility of C. ledgeriana is neither existing nor confirmed by Dr. Trimen in that manner.

Cinchona ledgeriana is the only cinchona that suffers from sterility, and only ripens more fruits, if it gets fertilized and hybridized by other cinchonas; that happens often, and therefore the descendants of ledgeriana are mostly degenerated, and the so-called ledgeriana bark of Java contains often very little quinine (till only 0·8 per cent!). Dr. Trimen says that "the seedlings [of C. ledgeriana] since Mr. Gammie uprooted nearly all the neighbouring trees come remarkably true, whereas before that was done the sporting was so great that Dr. King would not propagate by seed at all." No cinchona species shows a similar degeneration as C. ledgeriana if growing between other cinchonas; even the calisaya field of Mungpo shows yet a greater part of true C. calisaya. Dr. Trimen says nothing about the great fertility of C. ledgeriana, as Dr. Garcke supposes, but he gives an illustration of partly abortive fruits. I may refer to some other notes on the fertility of C. ledgeriana: Ledger wrote to Howard,‡ on the discovery of C. ledgeriana in Bolivia, "he then told me the best bark trees had not produced ripe seeds for four years," whereof frost cannot be the cause, for all other cinchonas there around ripened good seeds. In the "Berigte nopens de Gouvernements Kina Onderneming" (2 Kwartaal, 1874, No. 19) we read, C. ledgerianas give few seeds, and deceive us; the best trees were flowering to death. In the 3rd Kwartaal, 1875, from C. ledgeriana only fifty trees ripen sometimes a few fruits. In the 4th Kwartaal, 1877: the seeds of C. ledgeriana have failed. Visiting the Java and Mungpo plantations I observed also the poor fertility of C. ledgeriana.

As all other cinchona hybrids are always extremely fertile, I suppose C. ledgeriana must be an irregular hybrid—irregular, because the several qualities of the two parent species are not well combined as in the regular hybrids of cinchona. For instance, C. officinalis Hooker is the regular hybrid of C. calisaya and C. micrantha whilst C. ledgeriana is the irregular hybrid of these two species. Both hybrids have the broadest part of the leaves at or about the middle.

* 'Cinchona, Arten, Hybriden und Cultur der chininbaume.' Leipzig, 1878; Verlag von Haessel.

† 'Handwörterbuch der Pharmakognosie von Wittstein,' 1882, p. 131.

‡ Howard, "the Quinology of the East Indies, ii., iii., p. 48.

because C. calisaya has leaves with the broadest part below the middle, and C. micrantha has leaves with the broadest part above the middle ; C. officinalis, which also originated spontaneously in Mungpo, shows intermediate flowers and fruits with little variability, but C. ledgeriana possesses the flowers of C. micrantha and the fruits of C. calisaya. and shows great variability. Dr. Trimen confirms the great affinity of C. officinalis and C. ledgeriana by writing that it is indeed not always easy to distinguish C. officinalis from C. ledgeriana.

If we consider that (1) C. ledgeriana after its doubtless origin as a high shrub in the calisaya field of Mungpo must be a hybrid, (2) C. ledgeriana is a very rare plant of the American cinchona region, (3) C. ledgeriana shows only small fertility with its own pollen, (4) C. ledgeriana shows the best character of hybrids in preferring strange pollen to its own, as its typical degeneration proves, (5) C. ledgeriana shows only the specific qualities of C. calisaya and C. micrantha—we must conclude that C. ledgeriana is neither a variety of C. calisaya nor a distinct species, but a hybrid of C. calisaya with C. micrantha.

I gave two theses on the quantity of quinine in the bark relating to the hybridity :—

(1)—Only for the regular hybrids : the quantity of quinine increases by hybridity. For instance, the bark containing quinine averages¶ :—

I. C. Howardiana (Succirubra p. p.), 0·98 per cent.
II. C. Pahudiana Howard, 0·15 per cent.
III. C. Pavoniana (micrantha p. p.), 0·01 per cent.
IV. C. Weddelliana (Calisaya p. p.), 0·84 per cent.
IxII. (C. pubescens Vahl. Cordifolia Mutis, purpurea R. and. P., Coloptera Miq), 0·72 per cent.
IxIII. (C. heterophylla Pavon), no analysis existing.
IxIV. (C. lancifolia Mutis), 1·20 per cent.
IIxIII. (C. ovata Wedd.), no analysis existing.
IIxIV. (C. Humboldtiana Lambert, C. Hasskarliana miq.), 0·70 per cent.
IIIxIV. (C. officinalis Hooker), 2·58 per cent.

(2)—Only for irregular hybrids (till now only C. ledgeriana): with the greater irregularity, *i. e.*, the more the several marks of the parents are separate in the hybrid) increases the quantity of quinine. That is proved by my choice of the best sorts according to the botanical qualities of the many forms of C. ledgeriana in Mungpo, and confirmed by the analysis of their barks.

On the origin of the irregular hybrid I gave the following hypothesis, which must yet be confirmed by experiment: the pollen of a newly sprung hybrid fertilized the ovary of a species. As the regular cinchona hybrids of older origin seem to act like species, it would be better to prefer new or young hybrids. I recommended the fertilization with pollen of long-styled hybrid flowers on the stigma of long-styled parent (species) flowers, or with the pollen of short-styled hybrid flowers on the stigma of short-styled parent flowers, because the crossing of equal hetero-styled flowers acts like a hybridization and therefore the effects of hybridization must be increased. This is only a scientific hypothesis, but the experiment causes no extraordinary expenses to cinchona planters and it is easy to execute: as the stamens are inserted in the corolla tube it is only necessary to put away before the corolla is opened (or the pollen is not yet developed) the deciduous corolla from the flower whose stigma shall be fertilized, further to take the opened corolla with mature pollen of the hybrid and to put it over the isolated style of the other plant. The experiment promises great success by increased quantity of quinine, so that it may be recommended to all cinchona cultivators.

¶ Pharmazeutische Zeitung (Bunzlau), 1879, No. 93; Beilage No. 24.

Influence of Lime on the Germination of Seeds.—Some interesting results of experiments by Dr. Liebenberg as to the influence of lime on the germination of seeds, have recently been published in the *Journal of the Vienna Academy of Sciences*. It appears that the seeds of many plants require the presence of lime in the soil during the germinating process, or the seedlings die from want of it. It is likewise shown that many other plants do not fail to germinate freely and well without the presence of lime in the soil. Dr. Liebenberg also points out that plants which fail grow through the absence of lime in the soil do not fail in consequence of the injurious effects of any other matters that may be present, but because lime is essential to their healthy growth.—*Argus.*

Rubber in India.—We hear favorable accounts of the rubber trees sent to Nelambur and growing under the care and attention of Mr. Fergusson of the Forest Department. The Cæra is the only variety that has attained any size. The trees are eighteen months old, and are freely flowering at present. There ought consequently to be a supply ot seeds for distribution or propagation. The seed is large, and the shell is so hard as to make self-germination uncertain and protracted. With care, this might be effected in a year, but to expedite this important operation of nature, the bean should be rasped until the kennel is very nearly reached. When this is done, the seed will germinate in about three weeks.—*South of India Observer.*

Increase of Fruit Farming.—That fruit-farming is extending in this country is good news for all sorts and conditions of men. Particularly cheering is it for the farmer and the fruit consumer. The one has a new source of income placed within his reach, and the other is charmed by the prospect of cheaper fruit. The growing of fruit is extending very rapidly in Kent, the increased acreage under fruit in that county being, no doubt, due to the proximity of a certain remunerative market in the metropolis. There are now some 18,000 acres of fruit-bearing land in Kent—a truly remarkable icrease upon the 12.000 acres thus cultivated in 1875. The increase in the fruit acreage has been mainly in very recent years. In the five years between 1875 and 1880 the increase was only 2,645 acres; between 1880 and 1881 it was over 2,000 acres ; and between then and 1882 it further increased by more than a 1,000 acres.—*Land.*

The Number of Stock in Great Britain has of late years decreased to an alarming extent, and values have consequently advanced to an unprecedented figure. Imports from America mitigated for a time the scarcity, but the United States, from which supplies were chiefly derived can no longer bear the drain. Her own teeming and rapidly increasing population will consume all she can raise for years to come. Thrown, therefore, to a great extent on her own resources, this country must face the question boldly. According to Moorhull's Balance Sheet of the World, the annual consumption of animal food in Europe is 853,000 tons more than the production. England alone consumes 1,800,000 tons yearly, and yet she produces only 1,205.000 tons. This deficiency of 595,000 tons must be supplied at home. The inference is, more attention must be directed to stock-raising, and that too without delay.—*Downes & Co.'s Circular.*

Japan Black Tea.—Mr. Consul Enslie writes from Kanagawa (Japan) as follows concerning black tea:—This has, on the whole, proved a failure, although the production continues on a limited scale. The climate and soil of this country appear unfitted to the growth of plants producing a leaf of the quality necessary to make good black. Teas resembling good leaf congous can be made with good and even handsome leaf, several samples being in apperaance very similar to Indian teas of pekoe class, but lacking strength, and not being nearly equal to good Chinese Foochow teas in that respect. A small amount of these teas has been shipped to Germany on native account, a German financier providing the necessary funds; but thus far the outcome of these shipments has not transpired. The results generally of 1881 have not proved as satisfactory as those of the preceding year ; the whole crop, and more particularly the first picking, shews signs of hasty and careless preparation. The amount of tea exported from Japan was decidedly in excess of the requirements of the United States and Canada, and a considerable portion of the shipments for the year had to be sacrificed at prices which did not cover laying down cost.—*Indian Tea Gazette.*

FIBRE MACHINES.

Mr. H. C. Smith's new fibre machine is thus noticed in a letter from our old friend, Mr. Thomas Clark, of Messrs. Clark, Spence & Co., Galle, who, it will be seen, are agents for the patentee. The specimen of aloe fibre is very fine, but Mr. Clark seems not to be aware how largely we have discussed the subject of fibres and fibre machines. Aloes and pine-apple plants will yield excellent fibre, especially the latter, but we have not the same confidence as regards the comparatively weak leaves of the screw pine.

17, Philpot Lane, London, 26th January, 1883.

By way of renewing our very old acquaintance I am anxious to draw your attention to an improved scutching machine, which has recently been patented by Mr. H. C. Smith of Mauritius (now in England) for the production of aloe and other fibres.

I have noticed allusion in recent numbers of the *Observer* to the important increase in exports from Mauritius and Réunion islands of the *aloe*, and that several joint-stock Companies have sprung up of late years. I see no reason why this enterprize should not be extended to Ceylon. The plant grows almost throughout the island, and in the north I believe the coconut estates are fenced in with it.

Mr. Smith's new patent is applicable not only to the aloe leaf, but to the edible pineapple and *wild pine*, and perhaps I may include the plantain.

The patent is very simple, and one machine is capable of producing 600 lb. of clean fibre per day of 10 hours, and the present *value* on the average is about £36 per ton. I have sold two bales of superior at £42 per ton! Surely it is worth the serious attention of all who may have the raw material in the vicinity of their houses.

The cost of the machine is so trifling. It becomes within the reach of almost all; and you would, I am sure, be doing a public good by a favorable attention to the above remarks. Messrs. Clark, Spence & Co. of Galle are agents for the patentee.—Wishing you continued health and prosperity, believe me, yours faithfully. THOMAS CLARK.

As regards the Ekman process we have heard from a Colombo house that had made the needful enquiries, that the cost of the plant for this process is not less than £2,000! We see that some of the Mauritius "hemp" Companies estimate their produce all round at £32 a ton, but that they expect to work up to a fibre worth £40 a ton.

THE ADULTERATION OF QUININE.

Our London correspondent has recently referred to this topic, and we have received from an old Ceylon colonist, settled in Paris, a copy of the *Temps* of Feb. 5th, which contains an article on the subject. After giving a short sketch of the history of the fever bark, the writer refers to the alkaloids quinine and cinchonine, the action of the latter being, he says, uncertain. He then relates the experiments made by Doctor Laborde, the results of which are given in the *comptes rendus* of the Society of Biology of Paris. His first communication on the subject goes back to 4th Dec. last, and in it he recalls the fact that in 1877 he undertook experiments to determine the physiological action of quinine, cinchonine and cinchonidine, the toxical convulsing properties of the latter two being such that the effects were designated by him "cinchonic epilepsy." It was the recent epidemic of typhoid fever that attracted Dr. Laborde's attention to quinine, as he felt the necessity of determining the effects of a remedy so generally used. It was then that he first declared the quinine in use in the hospitals to be adulterated. At a meeting of the Society on 9th Dec., he reiterated and amplified his assertion, stating that the exact proportion of cinchonine in the quinine of the hospitals, determined by qualitative and quantitative analyses, was 43 per cent—almost half. He exhibited a specimen of the adulterated product, which had not the crystalline silky appearance of pure quinine but a dull cottony look. He also related experiments which he had performed with the substance on guinea-pigs, which proved the adulteration. At the sitting of 16th Dec. he again referred to the subject, and spoke of the necessity of an enquiry into the adulteration of the quinine supplied to the hospitals. Dr. Laborde's communication was reported to M. Baudrimont, the Director of the Central Pharmacy of the hospitals, who at first declared the adulteration to be impossible, as the quinine had passed through the hands of experts. However, he at once proceeded to test the statement of Dr. Laborde, which he found to be true, with this peculiarity, that in a certain establishment the quinine was pure, in another it was mixed with cinchonine in the proportions indicated by Dr. Laborde, while at another the bottles contained nothing but cinchonine. The Administration of Public Assistance, informed of the matter by M. Baudrimont, called upon the contractor, named Pressac, for an explanation; the latter replied that it was not he but M. Lacombe, the representative of the Lombard Manufactory of Chemical Products, who had supplied the drug. But the Public Assistance would not deal with the latter, Pressac having contracted to supply 70 kilos of sulphate of quinine at 370 fr. the kilo. They simply informed Pressac that they should lodge a complaint against him before the Public Prosecutor. Pressac hastened to Lacombe, who accompanied him to the Central Pharmacy, where he found visible proof of the adulteration in the boxes delivered on account of Pressac, which the latter had not even seen. It should be stated that cinchonine is worth 45 to 50 fr. the kilo, while 370 fr. was being paid for quinine. Lacombe was still more stupefied to find that in the boxes delivered by him in October and November the quinine occupied only about a third at the surface, the bottom being filled with cinchonine. The commission of experts had failed to detect the fund, so that the hospitals first served had received pure quinine, the next a mixture, or account of the effect of the shaking of boxes, and the last were supplied with pure cinchonine. The commission is composed of 14 persons of the highest respectability, and it is therefore impossible that they could have been parties to the deception. Lacombe, on being pressed by one of the experts, declared that the quinine was furnished to him by the Lombard Manufactory at Milan, of which he was the agent, and that the fraud must have been committed by them, but after the lapse of some days he wrote to the expert withdrawing his accusation, and stating that a mistake had been made in his own house. He confessed that he had mixed sulphate of quinine of a French house, of which he had two boxes, with the contents of the boxes from Milan. The French product having a better appearance than the foreign, he placed the latter at the bottom and the former at the top. But he was convinced that the latter was quinine, though he had since recognized that it was quinidine. He had mistaken the labels, and in support of his assertion he forwarded two labels meant for the two products and deceptive to the most experienced eye. This letter is at present in the hands of the *juge d' instruction*, who has been charged by the

Public Prosecutor with the investigation of the affair. The writer in the *Temps* then describes the method of extracting quinine, and says that the French manufacturers complain that on account of the duty on spirits in France ether costs four francs the liter, while the Germans pay only one franc. To this fact they ascribe their inability to compete with foreigners. The article ends by calming the fears of those ready to take alarm, assuring than that the test of the adulteration of quinine is an easy matter to pharmacists and chemists, and that, now that their attention has been roused, they will see that what passes through their hands is the genuine article.

By a later mail we have received the following from our London Correspondent:—

"Paris, Friday, Feb. 9th.—A politico-industrial discussion has been raging during the last few days between the French, German, and Italian papers, a discussion which threatens to become positively serious. There is a chemical manufactory at Milan which some time ago amalgamated with a German one. During the late typhoid epidemic here the Milan firm supplied a Paris house with considerable quantities of sulphate of quinine for the hospitals. It was suddenly perceived that this sulphate, which costs 450f. a kilogramme, was adulterated with a substance costing only 150f. The adulterated article was refused, and the French newspapers denounced German and Italian manufactures as fraudulent. This caused a great sensation in Italy and Germany. The manager of the Milanese factory hastened to Paris, and it was discovered that it was the Paris house that had substituted the spurious substance for the real sulphate of quinine—a fact which the head of the Paris house himself admitted in a letter to the manager of the Lombard factory. The latter has now commenced an action against the Paris house: but though the French papers, especially the *Temps*, have ackuowledged their mistake, the papers of Germany and Italy continue to manifest great irritation at an accusation which might have thrown discredit on their respective chemical products. The action, it is to be hoped, will put an end to a discussion which only tends to embitter the feelings between the three nations."

CINCHONA AND TEA CULTIVATION ON THE HILLS OF CEYLON.

With reference to the fact that twigs of some of our jungle trees act as poison to cinchona seedlings the question arises whether the influence of stocks and roots of such trees left in the soil may not account to some extent for the refusal to grow or the dying out of cinchonas? *All* the mischief may not be due to either climate or the conditions of soil, chemical or mechanical. The whole question of the effect of roots and stems of trees left to gradually decay in ground planted up with coffee, tea, cinchona, &c, is well worthy of investigation. Besides the general effect of rotting wood as a source of destructive insects and fungi, the directly poisonous action of particular forest trees on the various cultivated plants would have to be considered. The late Mr. Nietner collected much valuable information regarding the insect and fungic enemies of the coffee plant. We now want a supplement or a distinct treatise describing the vegetable enemies of our cultured plants, from ageratum and "wild mignonette" (the latter stated to be sixteen years old in Uva and six in Dimbula) to the loftiest of our forest trees which may be proved or suspected of doing injury, in its living or dead state, to coffee, tea, cinchona, &c. The deadly effect on tea bushes of the decaying roots of a forest tree, not yet identified by its botanic and native names, is unquestionably great, groups of from two to twelve plants being so poisoned to death. I see that an intelligent correspondent from the valley of the Peak traces paucity of feeding rootlets in the case of coffee trees to the enfeebling influence of the fungus. Although he also suggests a sour condition of the soil, I believe he might trace scarcity of bearing wood on the bushes to the same cause, the fungus. I have no belief in the theory of some planters that *Hemileia vastatrix* existed on coffee before 1869. Yellow leaves there were in plenty; but they were as different to the fatal copper-coloured masses of sporangia, as day is to night. I have no more doubt that the *chief* cause from which our great industry is suffering is the debilitating influence of the fungus which first developed on our cultivated coffee in 1869 than I have of my own existence. But grub has in many districts also done its part, and how far timber left in or on the ground to rot has been productive of mischief, in this and other ways, to coffee, and also to cinchona, tea, &c., demands full investigation. As bearing on the subject, however remotely, I may adduce the deadly influence of cultivated bamboos on coffee in their neighbourhood. Blue gums are also hurtful, and so are even cinchonas, especially succirubras when well-grown. As living trees are hurtful beyond what they produce of shade and drip—in a chemical sense—so dying and dead timber may be mischievous in various degrees. A set of analyses of soils and timbers and also weeds, proved or believed to be specially inimical to the healthy growth of our chief cultured products, such as coffee, tea, cinchona, cacao, &c., would be interesting and useful.

I am looking momentarily for a visit from our Mongolian mentor, "Cha" (strongly suspected of being a Scotchman of the *crooked nose**), and the first question I am likely to put to him is "Did you mean it, when you recommended the Rakwanaites to let *every third row* of tea grow up as a breakwind?" I believe in breakwinds, and in tea hedges along drains and paths and across hill faces, but to devote one third of a property to shelter belts takes me aback. If the system became general, tea seed would have to be expressed for oil and the cake used for cattle feed and manure. But "Cha," perhaps, intends that the shelter belts should themselves be partially pruned or at any rate topped at 5 or 6 feet high so as to yield some flush? Shelter hedges of tea bushes by all means, but surely not the extent of one third of an estate, however windy. In walking over young tea this morning, the mental note I took was that wind which had blown cinchonas almost out of the ground did not seem to have even checked luxuriant growth, except where the exposure was to the north-west. Tea will grow where cinchonas and even coffee refuse to flourish; but even tea shews in its aspect the effect of different soils, and we must not be surprised if, on a large scale, it hangs fire somewhat on those most promising but generally most disappointing eastern fronts in this district, as far as coffee culture is concerned. Isolated tea plants grown as tea seed bearers in such positions, however, have grown splendidly. Our experience here is that a good Assam hybrid grows much more readily than Assam indigenous trees, while some patches of China plants which we were at one time advised to eradicate, have "broadened down" into splendid flush-yielding surfaces. The present weather is all that could be wished for tea, and we hope soon to "speed the parting guests," in the shape of the tiny moth which lodges its grubs in the flush, and the leaf disease which has marked some of the more mature foliage with white dots. There must be something always to qualify sanguine feelings and we suppose we may thank ul if worse never overtakes our tea than the moth and the white spot.

Correspondence.

To the Editor of the "Ceylon Observer."

LIBERIAN COFFEE AT GAMPOLA.

Sinhapittia, 28th February 1883.

Dear Sir,—I picked off one Liberian coffee tree this morning 4,755 cherries. It was topped at 5½ feet the longest primary is 6 feet; the longest secondary 4½ feet; No of primaries 33; and circumference at 6 inches from the ground 13½ inches. I am sorry I did not keep an account of what I picked in January. It was at least 3,000 and there are more than 4,000 more on the tree. Do you think any tree in Ceylon could beat this?—Yours truly, E. B.

P.S.—Age of tree: between 4½ and 5 years.

CACAO DRYING.

Colombo, 14th March 1883.

Dear Sir,—I am much obliged for the hint given in last evening's issue regarding the reward offered in Trinidad for a cocoa drier. By a curious coincidence, just three weeks ago I sent to a friend in London the specifications and drawings of my drier and requested him to submit them to persons interested in the cultivation of cocoa in Trinidad and in the Spanish Republic, with the view of introducing the principle of the machines for drying cocoa in the way I suggested in a letter to the local "Times," copy of which I enclose for your *Tropical Agriculturist.**

* Cacao Drying.

Colombo, 24th Feb. 1883.

Sir,—My tea dryer can be applied to the drying of cocoa when it is necessary or advisable to apply artificial heat for that purpose. Though I have no experience in drying cocoa artificially, I am well acquainted with drying coffee in that way, as many years ago I used the Clerihew process on three estates I had at the time, and I know that though large quantities of wet stuff cannot be dried within a limited period on small heated areas, these may by rotation be made to do the work of large surfaces to which no artificial heat is applied, especially where, as in the case of cocoa, it is necessary to dry slowly. I have recently, through the kindness of the Ceylon Company, Limited, and Mr. Gavin Morice, been enabled to make some experiments in drying cocoa, and I think from what I have seen that in order to prevent the parchment or outer shell cracking from exudation of the moisture in the kernel, the drying must be gradual, and the heat should not be applied continuously. I am confirmed in this opinion by an experienced cocoa planter who informed me that, after the evaporation of the outside moisture, bright sun heat had the effect of cracking the parchment, thus rendering it liable to be detached from the kernel, which is the objection to drying artificially at a high temperature.

I have found that by heating the nibs to a certain point, and then putting them into bags or boxes for a time, the process of drying is gradual, and at the same time expeditious, without cracking the outer shells. It is unnecessary at present to go into estimates of the cost and capabilities of a drier 60 feet long by 4 feet wide, or calculate how much cocoa it would hold at a time, because I am sure no person would think of investing in a machine of that size without ascertaining its capabilites for himself by experimenting with small machines, the number and dimensions of which could be regulated by requirements and other circumstances.

One of the 8 feet by 2 feet dryers, three inches deep, costing about R40 heated to a temperature of 120 degrees would, I think, dry 4 cwt. in two days by rotating the charges every six hours or more frequently, two or more could be placed over the same fire which one cooly could keep up. C. SHAND.

P.S.—It should not be forgotten that the heat generated by these machines would keep a high temperature for drying purposes in a building constructed for the purpose. —C. S.

I believe the improvements being made in the construction of my tea-driers will admit of their being supplied on a large scale of durable and substantial materials at about two-and-a-quarter rupees per superficial foot of drying surface. Compare this with the cost of patent siroccos, and kindly bear in mind that, whilst the working capacity of these cannot be easily added to, the size of my driers may be increased as circumstances call forth.—Yours truly,

C. SHAND.

PEPPER CULTIVATION:—WANTED INFORMATION FROM THE MALABAR COAST.

Colombo, 14th March 1883.

Dear Sir,—Many of your readers will have read with much attention Mr. Dobree's valuable "Notes on Pepper Cultivation" (on page 801.)

As the writer of the queries on page 672, I beg to thank that gentleman for so disinterestedly placing the results of his study and observations before the public. And thanks are due to yourself for the very useful extracts appended to my communication of the above-mentioned date.

The information afforded thus far is opposed to the idea, a prevalent one here, that pepper will thrive in the jungle. It was to elicit information on this point especially that induced me to address you. Knowing the practice of the Chinese in this respect, on their plantations in Singapore and Johore, I was desirous of learning whether a different method of cultivation was followed on the Malabar coast, for I have found, on making enquiries here, that, where any knowledge of the subject is professed at all, the belief is common that in clearing for pepper only the undergrowth should be removed.

It any of your correspondents on the west coast of Southern India will describe the system pursued there, they will much oblige, yours faithfully,

LOWCOUNTRY.

TEA SEED—LOCAL AND IMPORTED—WHICH IS BEST?

C. P., 15th March 1883.

Dear Sir,—I should feel very much obliged to your correspondent "Cha," whose letters on tea are of so much interest to your readers, if he will give us his opinion on TEA SEED in general. I have been assured by experienced tea-planters that we are ruining Ceylon as a tea producing country by planting country-grown seed—seed off young trees, very often unripe, and trees of a bad jât. In fact, according to some planters, we are just following in tea the course we pursued in coffee and cinchona, and which has proved the ruin of many good men. Anyone acquainted with agriculture knows the evils arising from "breeding in and in," and that is what we are doing. The only excuse we can offer is: 'Oh, *Indian* seed is so dear and often turns out so bad, that we cannot afford to buy it." If this is so, would it not be better to leave tea alone? It is very gratifying to the owners of tea, bearing seed, to be able to make such handsome profits just now, but are they doing good to the colony by so doing? "Fools rush in where angels fear to tread." I fear there are a lot of fools still left in Ceylon, if what the Indian tea planters assert is true. Of course, *they* chuckle over it. With cheap labour, easy transport, and in some cases poor soil, of what avail will it be if our jât is bad?—Yours truly, ENQUIRER.

COFFEE DRIED IN THE CHERRY.

155 Fenchurch Street, London E. C., 16th Feb. 1883.

Sir,—Your correspondent "Mixed Products," on the 19th January, page 29, asks about Liberian coffee "dried in the cherry."

I have had over this from Liberia prepared both in the cherry and in the husk, but until lately it did not fetch a very high price, but of late things have changed very much. There is a market in England in which certain coffees fetch an enormous price, and the object of the buyer is to get as strong full-flavoured coffee as possible, because he wants to fetch up the flavour in the large amount of mixture which is sold as "coffee."

In manufacturing districts the poor people drink a much larger percentage of coffee than tea, and without milk. So far, the vendors of this trash have educated their customers' palates to a common coarse flavour, and I doubt if they would appreciate a pure coffee if put before them. For this reason it is well worth trying experiments. I ought to remind you at the same time that any of these special coffees are almost invariably sacrificed in the London market.

This is well borne out by the fact of some Jamaica plantation coffee fetching 183s per cwt., whereas in London this coffee, without it was recognised by the ordinary buyers, would pass almost unnoticed, if it had not a pretty berry.—I am, yours truly,

THOS. CHRISTY.

Indian Tea Statistics.—By this mail we have received from Messrs. Gow & Wilson, India Tea Brokers, a copy of a statement prepared by them on the above subject which gives a most hopeful view of India (and Ceylon) tea prospects. We shall quote the paper in full in an early issue.

Linnean Society, Feb. 1st.—Sir J. Lubbock, Bart, President, in the chair. Dr. W. C. Ondaatje called attention to examples of red coral from Ceylon.—Mr. W. T. Thiselton Dyer exhibited a model of the fruit of the double cocoa-nut (*Lodoicea seychellarum*, Lab.) of an unusual form, obtained from Major-General C. G. Gordon.—A series of microscopic sections of coal plants were shown on behalf of Mr. J. Norman.—The following paper was read: 'On the Structure, Development, and Life-history of a Tropical Epiphyllous Lichen,' by Mr. H. M. Ward: The author's observations lead him to believe that the epiphyllous cryptogam in question supports the view that a lichen is a compound organism composed of an alga on which an ascomycetous fungus has become more or less intimately affixed and dependent. It is developed on the leaves of many plants, but it has been more closely watched on *Michelia furcata*. The lichen presents four types—orange-red stellate patches, greyish-green blotches, clear grey spots, and white shining circles; but these pass imperceptibly into one another and vary in size from a speck to a quarter of an inch in diameter. The reddish spots of the earlier stages is an alga of which the radiating filaments are in part reproductive organs and in part barren hairs. It subsequently passes into the grey and green stages, and by a modification of growth the invasion of a fungus mycelium succeeds. The white matrix of the complete lichen consists of the same algal thallus invested by dense masses of the fungus hyphæ, which produce shining black dots, viz., the fruit bodies. The author describes in detail the peculiarities of growth and reproduction of the alga and fungus and the formation of the lichen. He alludes to and criticizes Dr. Cunningham's account of *Mycoidea parasitica*, which plant is evidently closely related to that described by himself Assuming that *Mycoidea* and Ward's alga are generically the same, either Cunningham discovered a female organ of reproduction which becomes fertilized and produces zoospores, he confounded this with fertile hair organs. As regards the systematic position of growth of the alga, a comparison with *Coleochoete* suggests that there is very little in common beyond the mode of the disc-like thallus and the production of zoospores from certain cells. The genus *Chroolepus*, moreover, presents features which agree in several important points, viz., orange-red oily cell contents, habitat, and production of zoospores in ovoid cells developed terminally and laterally. The structure of the thallus and the relative positions of the main masses of fungal and algal portions agree with what occurs in heteromerous lichens, as Graphidea, but the perithecia indicate its angiocarpous alliance, bringing the form nearer such families as Pertusaria and Verrucaria, to the latter of which it may ultimately be referred.—*Athenæum.*

Shand's Patent Tea Drier.—The following letter was received by Mr. Shand from Mr. C. Ross Wright:—

Barra, Rakwana, 2nd March 1883.

C. Shand, Esq., Colombo.

As stated in my last to you, dated 25th February, 1883, promising you a report of my trial of tea made on your patent steam heated tea-dryer, I have much pleasure in sending you my experience with it. Leaf dried on the model now at "Barra" Tea house has a most perfect appearance, as I have no doubt you will have already seen by the samples I sent you on Monday, 26th February, 1883. The samples were made on the 24th February, and the broken pekoe was valued by "Cha" *alias* W. Cameron, Esq., from 2s. to 2s 3d per lb. The leaf made into tea on this date was of the flushes after 4th round of plucking after pruning, and, having got a fair fermentation of ¾ red, and ¼ green, from 4 to 5 hours, with good temperature of 95° at noon was placed on the machine as follows:—

	taken in	time out.	in.	tea.
	p. m.	p. m.	m.	lb.
Fermentation 4 hours				
Put on broken pekoe on stove fire	2·5	2·40	35	¼
,, ,, patent machine	1·50	3·00	1·10	¼
Fermentation 4½ hours.	a. m.			
Put on pekoe on stove fire	11·50	12·37	47	¼
,, ,, patent machine	11·40	1·15	1·35	¾
Fermentation 5 hours.	p. m.			
Put on pekoe souchong on stove fire	1·20	2·30	1·10	6
,, ,, patent machine	1·5	3·40	2·35	¼

I find that the leaf dried on the patent dryer has to be put on some 10 to 15 m. prior to leaf fermenting, the same time as that to be dried on stoves, as fermentation continue to go on for the said time on the machine before it commences to be dried. The firing is somewhat slower than on the stoves (most excellent for final dryings, there is no chance of burning, and it requires but little supervision) the leaf on the machine before getting crisp (or shortly after putting the leaf on to the machine) is somewh- taken out of twist, but this does not apparently make any difference to the lookof the bulk.—Yours truly, C. Ross Wright.

Paper-Making in the Past.—Europe learned the art of paper-making from the Saracens, or Arabs, in the seventh century, who probably learned it from the Chinese. The process the Saracens brought to Spain, after their conquest in 704, had been in vogue in China over 1,000 years. The process was simply beating to a pulp, in mortars of vegetable fibre, and drying it in sheets. The Chinese make paper in the same way today, as they are opposed to the use of labour-saving machinery. The only machine admitted to the Flowery Kingdom is the Yankee sewing-machine. The use of paper for documents began about the tenth century. The use of rags for paper-making began in the eleventh century; prior to that, cotton, flax, &c, being used. The earliest record of the building of a mill for paper-making is 1370, the mill being erected in Germany. The mill was, however, only for reducing the fibre to pulp by stamps, run by water power, and was in no way like our modern mills. In 1588 a German made such good paper that Queen Elizabeth knighted him, and gave him a monopoly of gathering rags in the kingdom for ten years. The real value of paper-making began to be best appreciated when the art of printing was discovered, in the fifteenth century. Had printing been discovered earlier, there would have been little use for it, as neither the bark nor straw-paper of the Chinese, the papyrus of the Egyptians, nor the parchment of the Greeks would have been sufficiently plentiful for the demands of the printing press. Germany, using cotton, flax, and rags, and her water and wind power for their reduction to pulp and fibre, was ready for the printer and his press, and these made possible the Reformation.—*Printers' Gazette.*

[Has the time not come for manufacturing paper in Ceylon and Southern India?—Ed.]

AS TO HEDGE PLANTING.

TO THE EDITOR OF THE "INDIAN TEA GAZETTE."

Sir,—Would any of your readers enlighten me whether he tried planting on the *hedge system*; if so, with what result. This is quite distinct from close planting, which, with the soil and climate of Assam, is, I think, a mistake. I have planted 5 acres of land at 5' × 1½', putting two seeds to a stake. If there be no accommodation for the bushes to grow, I shall then cut the bushes, so that they may be 5' × 3'. There is in my neighbourhood a garden planted 6' × 6', from which the proprietors have got something like 7 maunds per acre this season. I wonder whether the yield would not have been 15 maunds per acre if the bushes were 4' × 4' instead of 6' × 6'. Yours, &c.—A Voice from Assam.

SHIPMENT OF TEA, AND THE WOOD FOR TEA BOXES.

Judgment was delivered by Sir Robert Phillemore. The learned Judge, after reviewing the facts, stated that the plaintiffs, to succeed in the action, had to show that either the cargo was shipped in good order and delivered in bad condition, or to point to some cause of damage for which the shipowners were responsible. The bills of lading contained the words "shipped in good order and condition" and the clause "weight, quality, and contents unknown." The shipowners by these words must be taken to speak only to the external condition of the goods and the packages containing them. The plaintiffs had proved that the tea itself was in good condition when shipped, but not that the cases were of a proper quality or in good condition. They had therefore endeavoured to show that the cause of damage was the foul condition and defective ventilation of the ship. The evidence as to the condition of the ship when the tea was put on board, given by the captain and officers and surveyors at Shanghai, led the Court to the conclusion that the "Asia" was in a clean and proper condition for carrying tea; and this view was corroborated by the surveys held in London on her arrival. As to the ventilation, the Elder Brethren were of opinion, and he agreed with them, that the ship was sufficiently ventilated for carrying a full cargo of tea; tea being a dry cargo and not liable to sweat. Some of the plaintiffs witnesses had also stated that tea damaged by want of ventilation lost its crispness, which it was admitted was not the case here. The plaintiffs had therefore failed to discharge the burden of proof that lay upon them. The defendants, on the other hand, had put forward a theory, which was supported by the evidence of eminent chemical experts—viz., that certain of the woods now often used in the manufacture of tea chests, when subjected to the heat of a tropical voyage, gave off acetic acid, which formed a deposit of acetate of lead on the leaden linings, perforating the lead, and combined with the smell of the wood itself, imparted a sugary smell and taste to the tea. Samples of the wood and lead had been examined and found to contain such deposit and perforations. The evidence of these witnesses was unshaken in cross-examination, and was to a certain extent corroborated by the plaintiffs' expert witnesses called in reply, and to his mind the theory seemed a consistent one. He, therefore, gave judgment for the defendants, with costs. —*Home and Colonial Mail.*

TEA—HOEING.

The year now in its infancy, will, we trust, be a more successful one for the Tea Industry than the one just ended; and at its close we hope we may be able to offer our congratulations to planters. To effect this planters must, as long as production is in excess of consumption, keep quality steadily in view. That this subject is nearly threadbare we are aware, but we contend that it must be reiterated. Last year was an extraordiuary one for the production of leaf, we are afraid, however, that quality was not kept in view, and hence, although we do not consider the fall in prices entirely due to coarse plucking or careless manufacture, we must plead guilty to believing that it was partly so, as the flushes came out more quickly than they could always be removed, and hence to some extent the deterioration of quality. Rapid flushes are more easily manipulated into good tea than slow ones, and in order to produce these, attention to cultivation is absolutely necessary. Hoeing, we are afraid, is often performed in a perfunctory manner, and as much attention is not paid to it as to some of the less important branches of cultivation. It is much easier to tell the Baboo to send so many men to the hoe than to go over each man's work carefully and see that the hoe is shoved in properly. The Baboo is delighted to show a fine surface all powdered down like a flower garden, entirely forgetting the important fact of shoving the hoe in six inches deep, and turning up the clods so as to show the reality of the work and obtain the full benefit of the first rains. Provided one could be assured that the hoe was actually put in, there is no objection to the smoothing over of the surface, especially on flat gardens; but we contend that the supervision such as gardens can afford, is not sufficient to go carefully over each day's work and see that a six inch hoeing has been given. In order to ensure as much as possible the reality of the hoeing, let the earth be turned up in large clods, which are standing witnesses of the reality of the work done. On teelah gardens this is also a great preventative of waste, as the early rains instead of running along the surface of smoothed ground, fill up the interstices between the clods, and before the second hoeing comes round, the surface is as a rule smooth. On teelahs as much hoeing as possible should be done round the teelahs. Many of the old teelahs were so planted that this is impossible, but where practicable it should be done. In former years, far more than is the case now, various expedients were resorted to, in order to prevent wash. In our estimation pitting and terracing are the most serviceable. Many people object to these as not giving room for cultivation, but it should be borne in mind that both these pits and terraces can be broken up in the cold weather and reformed preparatory to the opening of the rains, and that too with most beneficial results. That tea can be expected to go on yielding year after year without a good hoeing, is surely now an exploded idea, and we have no doubt but that substantial evidence could be adduced by planters that those who hoe deeply, be it on teelahs or flats, on terraces or pits, attain the best results both as regards quantity and, of course, a relative ratio of quality. The *chil chal* of a few years ago, we venture to hope, is now a thing of the past, and we also hope that the *kodali* or hoe now in use will soon be an obsolete implement replaced by a good substantial fork. In old gardens more especially harm is done by the hoe, as in very many instances the soil is so washed away that each blow of the hoe severs from the parent stem many useful lateral rootlets, and although all might not escape with impunity from the fork, yet the chances are that but few would be injured. We therefore recommend planters to hoe deeply and carefully, and to give as much attention to this simple operation as their other duties will admit of. —*Indigo Planters' Gazette.* [Forking and hoeing has been, and doubtless will be, the rule in Ceylon. Terracing is generally impossible, but pits at frequent intervals are feasible and ought to be resorted to.—Ed.]

NEW PRODUCTS IN THE NILGIRIS, S. INDIA.

GRASS—WATTLE—JALAP.

The following are extracts from Mr. Jamieson's report on the Botanical Gardens of the Nilgiris, and we call the attention of Planters to the excellent fodder-producer (Tagasaste.)—

Tagasaste (Cytisus proliferus).—Of all the plants with which I am acquainted none seem to have taken more kindly to the soil and climate of the Nilgiris than this shrub. The growth which it has made could not, I think, be exceeded in its native habitat. Many of the plants made a growth exceeding 20 feet in two years and have flowered and seeded abundantly. They were cut over at 2½ feet from the ground and have since pushed vigorous young shoots. This plant, I feel sure, would grow freely all over the Nilgiri Plateau and would be especially valuable in localities such as Kartary and Kalhatti, where grazing is year by year becoming more scarce. Mr. Christy, of London, in his pamphlet on new Commercial plants, makes the following remarks on the propagation and value of this new fodder plant: "The seed can be sown broadcast in the ordinary way. It is well to soak it in hot water for a few hours before sowing so as to soften it and allow the seed to germinate more quickly. When the plants come up too

thickly they should be thinned and those taken out may be planted somewhere else. They should stand one yard and a half apart. For the first two years the crop does not attain its full development, but in the third year the full yield of foliage is obtained, and continues thereafter. The plants may be cut twice a year. Tagasaste has the advantage of containing a large quantity of nitrogenous matter. It is estimated to coutain 1·136 of nitrogen against 1·028 yielded by the finest Clover hay. Each 100 lb of fodder is calculated to produce 2·60 lb. of meat. Animals fed on Tagasaste come into condition more rapidly and to a greater degree than with any other food except corn. The fodder is usually prepared by mixiog 35lb. weight of fresh Tagasaste with 20lb. of chopped strow. The amount is sufficient for the daily nourishment of a horse or cow. It is said the animals so fed fatten more rapidly with Tagasaste than with hay, which is thought to be due to the presence in the plant of an essential oil which is thought may retard the waste of tissue and thus cause fattening. On this account Tagasaste is recommended for feeding stock not intended for working." I have a quantity of seed and will be happy to give some to any oue willing to gave it a trial.

Black Wattle (Acacia decurrens).—In consequence of scarcity of good Oak bark for tanning purposes the attention of land-owners in the Colonies and India has lately been directed to the cultivation of Black Wattle as a remunerative investment. This Acacia is a native of the eastern part of South Australia and is a middle-sized trees of rapid growth. Its wood can be used for staves and other purposes, and it supplies an excellent firewood. According to Baron Muller good Wattle bark is three times as rich as Oak bark in tanning principles and is much quicker produced. Some tree of this Acacia have been grown in the Ootacamund Gardens for some years and thrive quite as well as the Silver Wattle (*Acacia dealbata*). A writer in a recent number of the *Australasian* states that in three years an acre of ground will yield 2½ tons of Wattle bark. The bark is said to be worth from £8 to £11 per ton in the English market. Seeing that there are immense tracts of at present unproductive land ou the Nilgiris, I would call the attention of such as contemplate planting Blue Gums for fire-wood, to this tree. Blue Gum, at all events in its green state, makes but inferior fire-wood, whereas the Black Wattle not only yields a valuable bark, but would, in the same period, give as much fire-wood as the Blue gum, and of a superior quality. If this tree were systematically planted on the Hills itwould doubtless prove a profitable investment. The cultivation of the Wattle is simple and easy, the seeds being sown either broadcast or in rows.

Jalap (Exgouium Purga).—The cultivation of this plant has passed beyond the experimental stage. and it is now an estalished fact that Jalap can be grown successfully in Ootacamund and will pay a fair return on the outlay even at the price allowed by the Medical Stores. The outturn of dry root was not so large as I anticipated or what it would have been had the tubers planted been allowed to come to maturity. But so long as I have to lift them to supply the public (*vide* G. O., No. 1637, dated 6th December 1880), it will be some years before I have a sufficient area brought under cultivation to meet the demand of even the local Medical Department, the annual requirements of which Surgeon-General Cornish puts at 1,200 lb.—*South of India Observer.*

NILGIRI BOTANICAL GARDENS.

The report on the progress and condition of the Government Botanical Garden and Parks on the Nilgiris for the year 1881-82, which was submitted by Mr. A. Jamieson, the Superintendent, in July 1882, has been published, with the remarks of Government thereon. The latter include the following:—"The delay in the submission of this report, which was due on the 10th July, is noted with disapproval. In future the Collector should forward the Superintendent's report at once with any remarks he may have to make. An elaborate covering letter on a technical subject is wholly uncalled for." We read that "during the year under report, 377 fruit trees, 2,348 timber trees, 7,950 ornamental trees, shrubs and herbaceous plants, 2,317 packets of vegetable and flower seeds, 85 bouquets, and 141 baskets of cut-flowers were sold by the Gardens. The gross income from the sale of seeds, plants, &c., from the several gardens was Rs. 3,026-10-4, and the expenditure Rs. 16,426." The growth of potatoes during the year has not been satisfactory, but the Superintendent has obtained some new and approved kinds from England which promise to do very well. He again calls the attention of planters and owners of cattle on the hills to prickly comfrey and Brome grass as fodder-producers. These fodder plants, he states, undoubtedly hold the first rank both as regards quantity and quality of their yield, and the ease with which they can be cultivated. A new fodder plant, tagasaste (*Cytisus proliferus*) has attracted Mr. Jamieson's attention, and he says that of all the plants with which he is acquainted none seem to have taken more kiudly to the soil and climate of the Nilgiris than this shrub. The plant would, he feels sure, be especially valuable in localities such as Kartary and Kalhatti, where grazing is year by year becoming scarcer. He has a quantity of seed and will be happy to give some to any one willing to give it a trial. Some interesting experiments with cinchona were tried. *Cinchona Carthagena* thrived very well, and the propagation of this valuable species has been so successful that a number of wellgrown plants and cuttings were handed to the Overseer of the Dodabetta Plantation. At Sim's Park *Ledgeriana* did not succeed, owing to the soil being unfavourable. Here some foresight and a little thought might have prevented what proved a useless experiment. It is well known—or should be—what soil *Ledgeriana* will grow in, and surely the Superintendent knew what soil he had to deal with in Sim's Park? There is no lack of literature dealing with cinchona cultivation. Owen's Manual is one of the best works yet published, and besides that one there are King's Manual, Markham's "Peruvian Bark," Mr. J. Ferguson's essay, and others. What Mr. Jamieson prized most of the new plants introduced were the *Castilloa Elastica* plants obtained from Ceylon, and which he has no doubt will find a suitable home in Wynaad, where it will probably yield a profitable return to the cultivator. The black wattle appears to thrive very well in Ootacamund and as the bark is valuable for tanning purposes while the timber is of a superior quality, the Superintendent of the Botanical Gardens calls the attention of all who contemplate planting to this valuable tree. The cultivation of the wattle is simple and easy. Perhaps we may soon read what the Conservator of Forests says about wattle, his opinion has been sought. Mr. Jamieson says of Liberian coffee:—

This excellent coffee continues to grow luxuriantly and yields annually more abundant crops than the ordinary coffee growing alongside of it. The Native estate proprietors in and around Barliyar are now, I am glad to say, beginning to recognise its superiority over the Coffea Arabica and are now planting it pretty extensively on their estates. There can be no question than in a climate like that of Barliyar heavier and more regular crops may be calculated upon from this species of coffee. Nearly half of last year's crop was stripped from the branches before ripening by the high winds in November. However, sufficient was saved to raise, nurseries and meet the demand for seeds.

Ipecacuanha has made fair progress, but has not increased in size and vigour, or made root growth sufficient to encourage a hope that it can ever be grown at Barliyar as an article of commerce. At His Excellency the Governor's request some plants are being tried in Ooty. Ceara Rubber trees have done very well, and there is a considerable demand for plants. The cultivation of Jalap has passed beyond the experimental stage, and it is now an established fact that Jalap can be grown successfuly in Ootacamund, and will pay a fair return on the outlay, even at the price allowed by the Medical Stores. On the whole, the gardens have been useful to the Presidency, but there seems to be something wanting; Rs. 13,000 per aunum should produce better results. The experiments are generally on such a small scale that a slight accident may at any time destroy all the Superintendent has got of any new plant, and thus delay the publication of information which may be of vast importance to the agriculturists of the country. Professor Lawson's advent will probably give a stimulus to effort in this department, and we understand he will spend several weeks at the Peradeniya Gardens, Ceylon, before arriving here. There a much larger sum is expended on experiments, and the receipts for plants and seed sold are much higher. —*Madras Mail.*

INDIAN TEAS.

[From "The Art of Tea Blending," the Melbourne edition of which has been edited by Mr. J. Moody.]

One of the most remarkable circumstances in connection with the development of the Tea Trade is the rapidity of the increase in the production of Indian tea. It is within the memory of many still engaged in the trade, that the idea of Indian being one of the most important branches of the business would simply have provoked a smile, and yet, in the year 1881, there were imported 44,585,000 pounds of Indian tea; and, large as this quantity is, it failed to keep pace with the consumption, which for the same year was 48,342,000 pounds. This is an increase of tenfold in fifteen years, and even in weight is nearly one-fourth of the entire deliveries of tea; while, should money value be taken as the test, the proportion would be much larger, as the price commanded by Indian tea is considerably greater than that of China.

The taste for Indian tea is rapidly increasing; here and there some even prefer it by itself. Nearly all Indian tea, upon its arrival in this country, is bulked—that is, the whole of the chests are emptied upon one heap and well mixed: this has the advantage of ensuring the regularity of the break, but as it allows the atmosphere to get to the tea, much flavour is lost, and decay hastened. This loss of flavour is much greater in some varieties than in others. The classes most affected are highly fired teas, light flavoury teas, and those that have a bold open leaf. The cultivation of tea is in India much more a matter of science than it is in the Celestial Empire. The Chinese, from time immemorial, have grown their teas on every little available space—sometimes on hillsides, sometimes on patches of land comparatively barren. They have used little or no manure; in fact, the son has followed in his father's steps, without attempting to excel. On the contrary, the growth of the tea industry in India has been fostered by many experiments—experiments as to the climate most suitable to tea-growing, as to the soil most congenial to it, and the manure by which it is most nourished; experiments as to the best methods of manufacture, and also experiments to ascertain the best kind of plant to cultivate. All these problems have been solved to a certain extent, but there is no doubt much progress will still be made. When, therefore, we consider the difference between a system of cultivation so barred to progress as that of the Chinese, and one so enterprising as that of the English in India, we cannot wonder that while Indian tea has been advancing greatly in public estimation, China tea has made comparatively little progress.

Each district extends over many miles, and comprises within its limits gardens in various stages of cultivation, and that the varieties of "hybrids" between the indigenous tree and the China bush exceed one hundred. There is one remarkable difference between Indian and China teas, and that is, while second, third and fourth crop China teas are different in character and respectively inferior the one to the other, there is nothing in Indian tea to proclaim its relationship to any particular crop or gathering. The number of times an Indian tree is plucked varies considerably, according to the position and soil of the gardens and the state of the weather. When all things are favourable, some trees will yield as many as sixteen or seventeen *flushes* (pickings), while occasionally only five or six can be obtained.—*Indian Tea Gazette.*

Assam Tea in Natal seems to grow readily enough, but, as we found in Java, the bushes blossom and fruit at too early a stage. In Ceylon, while inferior China blossoms and fruits at a very early stage, good hybrid Assam gives very little seed before the fifth year, and we know of some seven and eight years old, from which but little seed can be obtained. In Natal however, according to Mr. Hulett's very interesting account:—During the year 1878, the plants progressed most satisfactorily (*i. e.*, those that survived the drought of the previous summer) and by the time they had been planted one year, they were strong and vigorous. After they had been planted 18 months, or in May, 1879, the trees were large and substantial bushes. In the spring of 1879, or two years from planting, I took my first leaf, and attempted the manufacture of the same (many of the trees had, in the May previous, blossomed). I could not tell what amount of tea I manufactured from the 1,200 young trees (many of them were quite small), but sufficient for my own family purpose. However, being about to visit England, I took a few pounds with me for valuation, &c., (of which more anon). During February and March, 1880,* I picked my first seed, and carefully planted it; this seed produced plants which were placed out in November and December, 1880, filling up all vacancies in the original field, and making a total of about 5 acres planted to December 31st, 1880. At this time my original 1,200 plants were three years old, and giving me a good yield of leaf, whilst the trees had obtained a height of, in many cases, 5 feet with stems 2 inches in diameter. In February and March, 1881, I picked a large quantity of seed, which I planted for my own use, and from which I supplied the 27 acres planted this last summer. During the winter of 1881, or just one year ago, I tried my hand at pruning, but, being desirous of obtaining a good supply of seed, I only pruned 400 out of the 1,200 trees. In the spring following (last September), I commenced my first regular picking, and up to the close of the season, about 6 weeks ago, the 1,200 trees have given me over 500 lb. of tea manufactured, and more than half a ton of seed. Had these trees all been pruned I might reasonably have expected 100 lb. more, which would have given a yield of 1,000 lb. to the acre, and this before the plants had been out five years. As it is, my yield has been at the rate of over 800 lb. to the acre. Tea is not supposed to arrive at its full bearing power under eight or nine years.—*Indian Tea Gazette.* [The yield of leaf is very large, and if plants which have freely seeded at 3 years old are found to be lasting, then, certainly tea planting in Natal, with the advantages of Indian labour ought to be a success. Coffee proved a dead failure.—Ed.]

TEA AND SILK FARMING IN NEW ZEALAND.

TO THE EDITOR OF "THE COLONIES AND INDIA."

Sir,—You were good enough on February 10 to notice in your columns a paper on the above subject read a few days previously before the Society of Arts. Probably some of your readers may not be averse to learn a little more on the same topic, seeing that your Auckland correspondent of February 28, as quoted in your journal of May 12, endorses the main views of the writer.

Since the former date, it is not too much to say, that not only in New Zealand, but all over the sericultural districts of the world, a degree of fresh and lively interest seems to have been awakened in the future of silk production which augurs well for that important industry, and seems to promise, perhaps at no very distant date, to reinstate it with something of the magnitude it possessed before the climax of the various silkworm diseases in 1853. In the early part of this year, M. Federli, an Italian expert, who had been superintending various Government silk-rearing experiments at Canterbury, N. Z., forwarded a report to the Minister of Lands, in which he mentioned having inspected some silkworms reared by Mr. Nairn, of Christchurch, from a breed cultivated there for *thirteen years*, and found "no trace of any kind of disease." A few days later M. Federli gave his views at a meeting of the Christchurch Industrial Association regarding the promising prospects of sericulture in the Colony, explaining that it was a mistake to suppose that the industry required a large quantity of labour, a great saving in this important item being readily effected by the use of perforated paper.

About the same period I received a letter from the New Zealand chief Hone Mohi Tawhai, one of the Maori representatives in the Colonial Parliament, in which he stated his gratification at the efforts being made to promote the establishment of sericulture and some other subsidiary industries in his native province of Auckland. He also referred to the improving habits of his countrymen, to their aptitude in learning handicrafts which interested them, and expressed his wish to assist the proposed sericultural undertaking in every way. Coming from a man of mark, among his own countrymen as well as ours, and from a member of the legislative body, it will not be surprising if, under this native gentleman's influence and auspices, the labour difficulty may eventually be in a great measure removed. Another encouraging feature has been the establishment in Auckland, some eight or ten months ago, of the Thames Sericultural Association, to promote the production of silk in the district. At one of the preliminary meetings, accord-

* When the plants were not quite three years old.—Ed.

ing to the *Thames Advertiser* of January 28, such was the enthusiasm among the gentlemen present that some four hundred shares were subscribed for in the room. It may be as well to note, however, as illustrative of the slowness with which new ideas spread, that this ebullition of sericultural ardour took four years to develop, as the moving spirit and secretary, Mr. Albert J. Allom, of Parawai, Thames, N. Z., began his advocacy of the undertaking through the Colonial press as far back as 1877. Possibly somewhat of this pleasing issue may have been owing to the interest which for the past few years has been taken in the promotion of the industry by many in the parent country.

That the tea farming industry has also lately received considerable attention in New Zealand, one has only to glance through a file of local papers to be convinced. In testimony of this improved attitude towards the "cup which cheers," I shall only quote a paragraph which appeared in your journal of August 11:—"Some time since the Acclimatisation Society of New Zealand invited Mr Reid, a gentleman connected with the cultivation of tea in India, to make experiments with tea plants grown in the gardens of the society of Auckland. Mr. Reid has lately made his report, which is eminently satisfactory, and shows that the plant can be most successfully cultivated in that district."

These various items of news cannot, I think, but prove welcome to those of your readers who feel interested in the subject and in the progress of New Zealand. They may also have the desirable effect of stimulating such well-wishers and others to lend their assistance to an enterprise which seeks to combine the two industries of tea and silk farming there as being the most likely form for commercial success in a country where at present labour is scarce and expensive.

Among the distinguished Colonists to whom the advocates of this combined enterprise are indebted is the Hon. John Bathgate, M. P. for the Roslyn district in Otago, author of one of the best descriptive pamphlets on the resources and prospects of New Zealand which have recently appeared. This gentleman took occasion, on July 19 last, from his place in the Colonial Parliament, to ask the Government if they intended taking steps to give practical effect to any suggestions lately offered in connection with the culture of tea and silk in the North Island. The reply, though not altogether satisfactory, contained the important words —"The subject had been before the Government, and was now before them, and probably, when it took a more substantial shape, might yet be considered."

There are, of course, different aspects in which the word "substantial" may be considered. In the case of the proposed sericultural enterprise it means the formation of a company with a capital of not less than 150,000*l*., according to extent of field to be developed, with power to acquire eligible lands, forests, and running streams for water power, the erection of suitable buildings and machinery within the province of Auckland and elsewhere in New Zealand, for the purpose of conducting the farming and production of tea and silk, and any other articles of commerce found suited to the climate and locality. The offering of bonuses and other material encouragement for the development and stimulation of new industries, had long ago been a prominent feature in the policy of the New Zealand Executive, in common with the Governments of some of our other Colonies, so it was considered not unlikely that something of this kind might also be extended to sericulture and tea-planting. Accordingly, about two years ago the following openings for State aid were suggested to the Government:—

For the Tea Industry.

1. The necessary supply of one-year-old tea plants and fresh seed from China, Ceylon, Assam, the Neilgherries, and Darjeeling, delivered at the nearest port to the proposed plantations at cost price or free.

2. Facilities for the importation of labour from China, India, or elsewhere, and reasonable legal protection to the planter against the non-fulfilment or evasion of labourers' engagements.

3. A proportion of forest-land to the acreage purchased, or rented, at a reduced cost or free.

4. The admission, without duty, of all material, implements, tools, and machinery necessary in tea cultivation, manufacture, and packing, for a short term of probably ten years.

5. Freedom from duty or excise imposts for all tea grown and prepared in the Colony for the first ten years.

For the Silk Industry.

6. The necessary supply (400 plants per acre) of five-year-old white mulberry bushes grafted on black mulberry stocks, or other approved kinds and seed, from Sydney or elsewhere. Also the needful quantities of any other silk-worm-feeding shrubs, such as the castor-oil plant, the terminalia, jujube trees, the ailanthus, &c., delivered at the nearest port to the proposed plantations at cost price or free.

7. Facilities in regard to labour, land, and freedom from duties, as in the tea industry.

8. And such encouragement generally as might lead to the speedy settlement of skilled reelers from France and Italy, silk-throwsters from England, and the purchase in time of the mechanism required in the higher branches of the silk industry.

Such is the present position of this sericultural proposal. Its advocates having indicated to the New Zealand Government what they propose to do, and having specified as above several channels, in any one or more or all of which official aid might usefully be rendered, now respectfully await a decision. It is surely for the Executive to say, without further delay, in what direction, and to what extent, if at all, their assistance may be expected.

Meanwhile a manuscript prospectus of the proposed company is in circulation for additional suggestions and criticism, and I shall be happy to receive and register the names of well-wishers to the enterprise who may desire to co-operate in carrying it to a practical issue.—I remain, sir, Your obedient servant,

William Cochran.

Overdale, Dumblane, Perthshire, November 1, 1882.

ALOE FIBRE.

The depressed condition of planting enterprise in Ceylon has awakened there an anxious interest in the commercial possibilities of new products, and the climatic suitability of plants hitherto untried in the island. The cultivation of the aloe in the Mauritius has attracted attention in this connection. There the preparation of the fibre now takes second rank among the leading industries of the colony, and is rapidly extending; and though it has been advanced that there is some reason to fear that the limits of consumption for the quality now produced may soon be reached, when prices would necessarily suffer, there is the certainty of the demand stimulating the supply, when the fitness of the fibre had been determined for finer purposes than the manufacture of rope, in which it is now chiefly employed. It is a question of chemical malleability, and the extraction of the fibre by an improved method. The last is as yet most crude, and the former untried. Given such encouragement, as the requirements of India now offer in respect of the development of country manufactures by the utilization of indigenous products, and the accomplishment of the necessary desiderata, it goes without saying, must be quickly achieved. The description of aloe grown in the Mauritius is the *Fourcroya gigantea*, better known as the "*Yucca*" or Adam's needle of Jamaica. It is of very hardy growth, requiring no attention, and will continue an abundant yield of leaves for several years. Drought has no effect upon it, and it gross luxuriantly in arid land that has been thrown out of cane cultivation. It is propagated either by seeds planted at stake, or by means of young plants from twelve months to three years old; they are put into the ground five feet apart. If grown from seed, they require five years to attain their full size; but if plants, 18 inches high are put in, they mature in three years. On an average they blossom in seven or eight years; they can therefore be cut only four or five times. There is another description, the *Aliafolis*, common everywhere in India, and familiar from its formidable array of long hard flattened leaves, which tipped with a needle-like horn, bears in the rains countless white flowers, hanging most beautifully like little bells from its neat growing stem. The American aloe is more of a garden plant, luxuriating in leaf mould, and from a richer soil derives a superior fibre. But there is a conflict of statements with regard to its marketable value. Messrs. Cantwell & Co., of Calcutta, who bring to the notice of the public that they have an inexpensive and simple method of extract-

ing the fibre, "adapted to the circumstances of the ryot," obtained a valuation of £28 per ton on a sample sent home by them; and their advice "also stated that the highest prices that any aloe fibre has hitherto realized in the London market, was £16 per ton." If this be so, the statement contained in the *Planters' Gazette* of November 16th, published in London, that the market, "after rising from £30 and £32 to £38 and £40, has declined to about £33 to £35 per ton," is misleading; unless such has been the condition of the market at a subsequent date, a jump in prices hardly credible; and it is disappointing that the *Planters' Gazette* quoting Messrs. Cantwell should have overlooked the discrepancy in the figures noted by us. But, whatever the commercial value in London of the fibre of the aloe, whether of the American species or the "*Yucca*," there can be no doubt of the remunerativeness of the cultivation of either in this country, where the times give promise of the establishment of a variety of mills for working up-country produce. It is estimated, though this is necessarily guess work, that a beegah yielding 50 maunds of clean fibre would at a market value in Calcutta of R8 per maund, give a return of R300 per annum, all costs being calculated at R2 per maund. In places where there are tracts of waste ground, the experiments may be tried on a larger scale, and perhaps where reh has exterminated every other vegetable product, a plant so hardy as the aloe may find root and live. We do not know; but planted in hedgerows, the aloe provides an impenetrable fencing for cattle, and in the day of pruning will give a handsome return. It is interesting at this point to consider the manner in which the fibre is separated from the leaf in the Mauritius. This is by a machine known as the "Gratteuse," of which an idea may be conveyed by the possibility of converting the old-fashioned coffee pulpers in Ceylon to the same use. But, in detail, pieces of 2-inch angle iron screwed across a drum at regular distances from scrapers, which in revolution comb the fibre off one side of the leaf. An adjustable sloping breat or chock placed a little below the periphery of the drum supports the aloe leaf, which is introduced from between two rollers, against the scrapers. This breat is three-quarters of an inch thick, and is sloped off exactly like the innerside of a thumb. On this surface the leaf is combed, the chock being adjusted as required. There are 18 scrapers to each drum. When one side has been done, the leaf has to be withdrawn to present the other side. This is primitive enough, and with the steam power generally possessed in indigo concerns, any number of these machines may be driven. But it is exactly in respect of the manner in which the fibre is extracted, that its value is affected, and given as we have said, the circumstance of a large demand for a fine quality, fibre fine enough for spinning and superior paper, it can be confidently looked to that the Mauritius method will be improved out of recognition.—*Indigo Planters' Gazette.*

The Silkworm in Ceylon.—A few years ago one of the Society of Arts' lecturers stated that scruples of a superstitious nature among the Buddhists of Ceylon had interferred to prevent silk culture becoming popular there, although the priests themselves did not hesitate to wear robes of the beautiful material. Since then those scruples have either disappeared or the sacerdotal teachings have lost their efficacy with the natives. Sericulture is now being pursued with considerable success in some districts of the great, yet unfortunate, coffee island. Among other amateur silk-farmers Father Palla, at Galle, has recently endeavoured, by the promotion of mulberry and silk culture, to open up new fields to the industry of the people. It appears that a demand for eggs produced in his magnanerie has arisen in Europe in consequence of the favourable impression created by samples of his cocoons lately sent over, which for size and beauty were much eulogised. Unfortunately there are obstacles to the prosection of the silk industry in Ceylon in the shape of the too abundant insect, reptile, and rodent life which keeps the island always lively; so that the worms apt to be victimised by scorpions, wasps, ants, lizards, rats, and other obnoxious creatures. But by the exercise of the precautions usual in every tropical climate against the inroads of vermin, the attacks of those enemies will doubtless in time be frustrated. Farther from the equator the risks diminish. Indeed, it is one of the merits of comparatively temperate countries, like the northern portion of New Zealand, that sericulture may be followed free from exasperating agencies. The whole surroundings are such as to render the light, agreeable, and charming industry of silk-farming equally alluring to old and young.—*Colonies and India.*

Kola.—At a meeting of the Linnean Society, December 21, Mr. T. Christy called attention to some experiments lately made, which show that the Kola nut possesses singular properties of clearing fermented liquors. Mr. W. B. Espeut, of Jamaica, also assured the meeting that it was a certain specific against drunkenness, sobering the individual very rapidly. Quite lately there has been advertised Kolanut Beer, and the maker states it to be superior to Bass's and Allsopp's famous brands, with nonintoxicating qualities and stimulant power of a high order. We would recommend Kola to the notice of the Yellow Riband Army.—*Gardeners' Chronicle.*

Cinnamomum Tamala.—In the Palm house at Kew there are two fine specimens of this interesting Indian tree now in flower. The flowers, though produced in profusion, are, on account of their small size and lack of colour—greenish-white—somewhat inconspicuous; the foliage, however, somewhat makes up for the lack of beauty in these, particularly when the young growths are developing, the leaves then being a delicate pink. At present they are bright glossy light green in colour. This tree is somewhat widely distributed on the Himalayas, where it is found at elevations from 3000—7800 feet feet above sea level. It is not gregarious, but is scattered in the mixed forests, and generally affects shady moist glens. The bark, especially that of the root, is medicinal, and is largely collected and sold under the name of Taj. There is also a considerable trade done in the leaves, which are sold under the name of Tezpat and Tajpat. According to some authorities this species—but which also occurs in Queensland—is a source of Cassia lignea of commerce.—*Ibid.*

The Trees of Madagascar.—The soil is most fertile, producing rice, manioc, sugar cane, pepper, cotton, indigo, tobacco, and a variety of medicinal plants. A range of fine mountains divides the island into numerous well watered valleys. But the great glory of Madagascar is her magnificent forests, stretching over two thousand miles, and containing the most beautiful and valuable trees, on which grow creepers and orchids of the rarest kinds. Among the trees are the pandanus, the acacia, the sago and the cocoa plam; but the most remarkable one that has been discovered in Madagascar is the *ravinala*, or traveller's tree (*urania speciosa*), which covers large tracts of the forest. The Rev. W. Ellis, speaking of this tree, says:—"It rises from the ground with a thick succulent stem like that of the plantain, and it sends out, from the centre of the stem, long broad leaves like those of the plantain only less fragile; and rising not round the stalk, but in two lines on opposite sides so that as the leaves increase and the lower once extend horizontally, the tree presents the appearance of a large open fan. I frequently counted from twenty to twenty-four leaves on a single tree, the stalk of each leaf being six or eight feet long and the broad leaf itself four or six feet more. These bright green gigantic leaves spread out like a fan at the top of a trunk thirty feet high, and present the most magnificent specimen of vegetation that can be conceived." But it is not only for beauty that this tree is so remarkable. It is used for almost everything (like the palm to the Arabs in the desert), but it is most valuable from its containing, even in the driest season, a large quantity of pure fresh water, supplying any want of wells or springs to the traveller. There is a kind of natural cavern or cistern at the base of the stalk of each of the leaves, above its union with the stem, and on piercing this a stream of pure clear water gushes out, which is cool and perfectly sweet. The leaves of this tree from the thatch of the native houses, while the hard outside bark is used for flooring. These leaves are sold in all the markets and are used as plates, dishes, table cloths, wrappers for packages, and even when folded into certain shapes, as spoons and drinking cups.—*Month.*

A Pear Tree Regularly Bearing Two Crops Annually.—A correspondent of the *Garten Zeitung*, hailing from Kirchheimbolanden, in the Palatinate, states that some six years ago the owner called his attention to a Pear tree, which he asserted regularly bore two crops a year, and this has actually been the case during the last six years, sometimes bearing few and sometimes may in the second crop. The tree is a healthy, vigorous one, probably from forty to fifty years old, and bears yearly. The first crop ripens at the end of August or middle of September, the fruit being of medium size, Pear-shaped, and well-flowered. The second blossoms appears on the tips of the young twigs about the middle of June, and the fruit, which is only a third the size of the first, ripens in October, and is equally well-flavoured as that of the first crop. In conclusion, the editors mention other instances of the phenomenon, and it is stated that Berre Perpetuel invariably does, as Napoleon sometimes does with us.—*Gardiners' Chronicle.*

The Trade in Wood.—Messrs. Churchill & Sim state in their annual circular that the consumption of wood in the United Kingdom in the year 1882 appears to have been large, for after an importation of more than 6,300,000 loads as compared with 5,600,000 loads in 1881, stocks generally, so far as it is possible to ascertain, are not heavier than at the commencement of the year. The total importation of foreign deals and battens has been 11,804,000 pieces, of which Sweden contributed 7,073,000. The dock deliveries have been 10,843,000, pieces, against 10,991,000 pieces in 1881. Mahogany.—The trade of the past year has been generally of a satisfactory character; prices, which were firm at the commencement of the year, have shown no great fluctuations, but remained fairly steady until the autumn, when it became evident that the supplies would again be light, and figures then advanced, especially for straight, sound logs from medium to large sizes, which have been and remain very scarce. The dealers and yard-keepers, having no accumulation of stocks, have throughout the year been ready buyers, and the auction sales have therefore been well attended, and as a rule showed considerable animation; prospects are now encouraging for importers. The total number of logs landed is almost identical with the previous year, being 29,435 logs as compared with 29,678 logs; but the consumption having increased nearly 8 per cent., the stock is now 36 per cent. less than at the commencement of last year, and lower than at any corresponding period since 1872, being only 5758 logs or little more than two months' average consumption.—*Ibid.*

Maize *vs.* Coffee in Brazil.—The "Rio News," in directing attention to the maize exports of the River Plate, a large quantity of which are introduced into Brazil for popular consumption, advocates the home growth of maize in the Imperial territory, where considerable tracts of country are well adapted for the profitable cultivation of of this cereal product. We quote as follows:—Maize is fast becoming an article of regular import from the River Plate, where its cultivation is an industry of very recent date. On the 10th inst. one steamer alone, the "Mozart," brought 7,200 bags of maize from Buenos Ayres for this market, and the trade is steadily increasing. The question arises therefore, why cannot this local demand be met by local production? Maize is an article of prime necessity, and the demand for it will be constant. A large area within easy distance of market is well suited for its cultivation, and the industry requires few tools and no machinery. It is a product which can be cultivated on small plantations, by small planters, and in places where the more expensive cultivation of coffee or sugar cannot be carried on with profit. It needs no other capital than land and labour, and its market is constant. In view of the fact that coffee is fast becoming an unprofitable crop under the present system of production it would seem eminently wise that steps should be taken to substitute it in great part by other industries, and among them the cultivation of maize. At the River this industry has increased so rapidly and has gained such proportions that the excess fo production this year avaiable for export, is estimated to be not less than 200,000 tons. And yet labour is probably no cheaper there than here, and there are many localities in Brazil capable of producing fully as well as those of the Platine republics. What is needed is a proper encouragement of the smaller industries, and the suppression of that mistaken opinion that the agricultmre of the country is dependent upon the *grande lavoura* and servile labour. Free labour, small culture and diversified industries will do more for Brazil that the best system of great proprietorships ever known, and with them will disappear that economic anomaly of an agricultural country importing the greater part of its food from ahroad.—*South American Journal.*

Casuarina Trees (*Casuarina Muricata*) are thus noticed by Mr. Robertson of the Madras Government Farm:—The plantations continue to thrive. An account has been opened for each plantation, and it is hoped that data will be collected, which, will be of use in showing the cost per ton, of the fuel produced under different systems of planting. At an auction sale held in February, 100 trees were sold for R194-4-0, nearly 2 rupees per tree: the buyers cut down the trees and removed them, at their own expense. None of these trees were over ten years of age. Some were under eight years. Another lot of ten trees were sold by weight; they weighed 3,796 lb., and the price obtained for them at R9 per ton, with one rupee obtained for the roots was R16-4-0, or R1-10-0 per tree. Of course, the trees cut down were the best in the plantations. The object in planting the land with Casuarina trees, was chiefly to improve the soil, and to utilize land, which for arable tillage was almost worthless. The intention is, to plant the land with fruit-bearing trees, such as guavas, mangoes, &c., as the Casuarinas are removed. During the year 8·93 acres of poor sandy outlying land were planted with Casuarinas.

Reana Luxurians.—Of this fodder, Mr. Robertson of the Madras Farm, reports:—This was grown as an ordinary field crop. The outturn of both fodder and grain was good but the weather during the experiment was unusually favorable. On good soils, under liberal treatment, when it can obtain plenty of rain or irrigation water, the crop growth most rapidly and luxuriantly; but it cannot withstand a drought. Indeed, the experiments made showed that a drought, which scarcely affected the sorghum crops, was sufficient to check the growth of the Reana to such an extent, as to render it useless to keep the crops standing longer. As a fodder crop, in a damp warm climate, or where irrigation can be secured, it is well worthy of attention. There is perhaps no other crop, sugar-cane excepted, which will produce such an enormous quantity of green plant per acre, but the fodder is very watery, and does not appear to be very palatable to stock when offered for the first time. The watery juices of the stem, appear to be destitute of saccharine matter, during all stages of growth. The grain is almost useless as food.

Nitrate of Soda and Guano.—From Messrs. W. Montgomery & Co.'s report we learn that during the past six months there have been several considerable fluctuations in the market price of nitrate of soda. On June 30, when the half-yearly statistics were gathered together, a very large consumption was found to have taken place, and under the influence of this and consequent small stocks in the various consuming markets we experienced a brisk demand at advancing rates during the summar months; untill in August 13s. to 13s 4½d was paid for cargo-sailing between June and November. This advance was however, quickly checked by reports of increasing shipments, and when the figures for September—October were generally known there was something like a panic in the cargo market, values being depressed in November to about 11s. 9s. per hundered-weight U. K. for autumn shipments. From this point there has been a decided recovery, chiefly owing to heavy buying on the part of a clique of operators who considered prices unduly low, and who consequently may be supposed to take a favourable view of the ability of the European markets to consume during the coming season the very ample supply now in view. That supply is an unprecedentedly large one, but so on the other hand has been the demand during the past twelve months. Indications are not wanting to show that the shipments for the future may be maintained at about the rate of 450,000 tons per annum. Peruvian guano.—The total imports into Europe during the past half-year amount to about 35,000 tons, principally of low quality containing from 4 to 6 per cent. ammonia, and from 40 to 50 per cent. phosphate of lime.—*Gardeners' Chronicle.*

NORTH BORNEO OR "NEW CEYLON": THE SABAH GOVERNMENT.

Diary of Mr. Von Donop travelling through the Country.

To the Editors of the "Ceylon Observer."

Sandakan, 3rd January 1883.

Dear Sirs,—I have been intending to send you a *short* account of another trip through North Borneo for some time, back, but no opportunity has offered till now, I having to wait till weather clears up in order to get back to my headquarters at Selam.

On July 30th I left Kudat in the Company's launch "Mongelas" accompanied by Mr. Saunders, an experienced tobacco planter from Deli, who was anxious to ascertain whether this country was suited for that product. Our destination was the bay of Abai, situated on the west coast, which place we reached towards evening: but owing to the bar and low tide we were unable to enter till night. Abai had always been pronounced one of the pettiest Residencies of the Company and certainly it is very picturesque. The Government house, which lies quite close to the shore, has a beautiful green background, upon which several hundred head of cattle all in the pink of condition were to be seen grazing.

July 31st.—We landed and put up at the Residency, which happened to be unoccupied and made ourselves quite comfortable. During the afternoon two of the headmen from Jampassuck, which is about six miles distant, came over to pay their respects, and I at once questioned them about supplying me with men as carriers to go inland. The result was not very encouraging, as they told me this was a most unfortunate time of the year to procure them, as the men were all busy preparing their rice-fields; but that they would do their best for me and let me know on the morrow. After they had made their departure I crossed the river with Mr. Saunders to see some Liberian coffee and some of the Arabica kind. I found them without much difficulty growing under heavy shade and choked by a good deal of undergrowth. The Liberian variety was about 8 ft. high, but, owing to the shade, growing in a very lanky fashion. The Coffea Arabica was growing in native fashion and had not a very healthy appearance. I pruned them out a bit and topped the Liberian trees and then hacked some of the jungle to let in more light, from which they ought to gain great advantage. From here we took a stroll in the direction of the Jampassuk plain, which appeared very extensive. Parts appeared covered with a fodder grass and other with lalang. The soil appeared rather sandy, but I put off a further inspection till the next day.

August 1st.—We followed today the same tracks as yesterday. On nearing the old Jampassuk Residency, the soil appeared to be much richer than that in the Abai direction, there being also several fresh-water springs. Arrived at the Residency I sought out the little coffee (Arabica) garden, which was neatly enclosed in a fence. The trees were growing in native fashion and had a fair crop upon them. I could find no disease, every one of them looking most healthy. I gathered some of the ripe cherries, which, on testing on my return to Abai, appeared to have a large percentage of light coffee, but this would be expected, seeing it is growing about 50 feet above the sea in a sandy soil and under the shade of the tamarind, tree. The Manila hemp which I next went to see I found smothered up in scrub, but it nevertheless looked well and I expect to get several hundred shoots from it. The natives told me that formerly it was grown on an extensive scale, but that cheap cotton goods had done away with the necessity for its cultivation.

I also saw the shoeflower growing and flowering well, so that residents in Borneo will be able to obtain a very pretty shrub for making garden fences. I thought in getting sapan seed from Ceylon I was introducing a new and valuable product, but I found it growing here, though on a small scale, the natives using the dye for ornamenting the coils of rattan they wore round their hips.

Crossing the Jampassuk river we again entered a large and extensive plain, the soil appearing very rich. I went into one field where I saw a man ploughing, and it struck me he would get very good returns for his labour.

The river runs all along this plain, which could, if necessary, be easily irrigated. Passing on we arrived at the chief's house, whose name is Data Tomangong. He quickly brought a gaudy mat with cushions and requested us to make ourselves comfortable. A chief's house is rather interesting. Most of the space is taken up with large mosquito curtains, and inside each of them is a luxurious bed, consisting of a pile of mattresses and cushions, with a number of handsome boxes, brassware, old Borneo guns, etc., which form a rather queer background. Mrs. Data soon came to the front with a cup of tea and some sweet cakes, and, while refreshing ourselves, I made enquiries about the promised men, but found to my regret nothing as yet had been arranged. The chief informed me that the men all say: "If we don't sow our paddy we and our families will all die," but that he would still try to get some for me. We therefore said good-day and returned to the Abai. I learned afterwards that what we thought was tea turned out to be liquor made from a creeper called the *Lecatty Lema*. Neither Mr. Saunders nor myself could distinguish the difference between it and *China* tea.

August 2nd.—Started from the Abai soon after 6 o'clock to have a look at the plains to the south of Jampassuk. They were mostly rich in soil and here and there I noticed a small commencement had been made for planting paddy. On my way back I called on Data Rumbungan, and he told me he had got me three men and that he heard the other Data had got two and that most likely I would be able to procure as many more men as I required at Ginambur, a village on my route. I therefore decided to send back the launch to Kudat and do my best with buffalees and what men I can get and make for Ginambur. I also intend to come over and put up with the Data, as I can make better arrangements on the spot.

August 3rd.—The launch left early for Kudat, and after it had gone we loaded two or three buffaloes with our luggage and started for Jampassuk. Arrived at the chief's house, we found him out, but made ourselves comfortable all the same. The old man came in towards evening, he having been hunting men for us and got he said a fair number who would arrive in the morning. The scenery round about his house reminds one very much of a nobleman's park. Large timber trees intermixed with fruit trees of all descriptions with cattle grazing on the grass beneath, combine to give the place a very picturesque appearance. We smoked and talked till late at night and then turned in. I fortunately had a mosquito curtain, but Mr. Saunders unfortunately was without one and suffered fearfully.

August 4th.—Shortly after six o'clock our men numbering about 20 arrived and then commenced the business of packing each man's pack and seeing that each had the right weight and taking an account of what each man had. This being at last accomplished, I bade farewell to the Data, gave his wife a small present, and then we commenced our march. This route is the same as was taken by Messrs. Low, St. John, and Burbridge on their way to Kinabahu. It was a very hot walk over the plains to Ginambur, a miserable little village. We arrived at it towards evening; but luckily it was close to the river and we were able to get a very pleasant bath. Just as we were going to sit down to our evening meal the news arrived that the buffalo carrying our rice had breathed his last in a pool some three miles distant. This was most amazing, as I did not like to send the men, who had bad heavy loads and were naturally tired, back for it. Fortunately the Data happened to be following us on his way to market and brought us sufficient rice for the evening meal and sent back buffaloes for the remainder. Our abode for the night was much more humble than that on the preceding night.

August 5th.—Got a few more men and loaded them with rice and then commenced our day's journey, which was principally along the banks of the Ginambur river, the country being principally chena. Owing to the fine weather the river is low, but I can easily imagine what a swollen torrent it must become when the heavy rains commence. A small mountain called Parie Pair is always before us; it shews signs of cultivation most of the way up. Just, before reaching a village called Tambutuan I saw paddy

which was irrigated from the river, embankments of stone and mud having been made. Each little square I noticed was kept free from weeds while the paddy looked remarkably well. I wanted to reach Kian today, but owing to the late hour at which we started in the morning I found it impossible, so I decided to stop the night at Tambutuan, but to reach this spot we had to climb a hill of 1,200 feet. It was very steep, but I was able to gain some idea of the soil, which was what I wanted. Arrived at the top I found I was monarch of all I surveyed, so sat down and waited for some of the men. At last my servant and interpreter Sandy arrived, and we entered the village, found the headman at home, who welcomed us to to his house. We quickly made a raid on the coconut trees around us, and having changed our clothes were soon as comfortable as we could be. The neighbours around came pouring in to see us, and Sandy, who had been here before with Mr. Burbridge, found numbers of old acquaintances especially of the female sex. The old chief was great fun and we smoked and talked till very late. Master Sandy I found was also spending a pleasant evening from the shouts of laughter that came from the next room. I had the curiosity to look in while passing, and found him surrounded by an admiring crowd of girls whose fortunes he was pretending to tell.

August 6th.—The chief was very anxious to go through the ceremony of making us his brothers, but, as I knew we would have to give him a suitable present in return I declined, as we must economize our stock of barter goods, which consists of beads, dark blue cloth, white cloth, needles, small looking-glasses, and a few coloured handkerchiefs. Our descent was if anything too early accomplished, there having been a heavy dew overnight. Arrived below we followed our track of yesterday. Before reaching Kian we came across what must have been an old village, as a few coconut trees, sago, etc., etc., were to be seen. From the appearance of the land round about I should say they had moved on to some other place owing to the land being exhausted. We arrived at Kian about 10 o'clock, a small but pretty village on the banks of the river. From the number of young people amusing themselves in the river it would appear to be washing day. I did not care to stop as I wanted to reach Kian before night, so passed on and waited for my men in the river. From here I obtained a splendid view of old Kinabahu. Passing on again we met several parties travelling down from the Kian direction with tobacco, potatoes, etc., which they were taking to barter for rice. They seemed to think naturally we were making for Kinabahu. In crossing the river a little farther up we came across the chief of Kian with plenty of men. We had a short talk and then he acted as guide to Kian. The finish of our journey yesterday was steep but nothing to the one today—a short cut up through some patna to 2,900 feet. Arrived however at the top we were rewarded with a splendid view of the surrounding country. The chief's house looks down the valley which we have been travelling up and very little jungle is to be seen, but behind us Kinabahu has a good supply. The old chief mentioned by Mr. St. John is dead and another reigns in his stead. My object in coming to Kian was to ascend Kinabahu as far as 4,000 or 5,000 feet, and see what the soil, jungle, etc., were like, but I find it is impracticable, as we cannot beg a grain of rice here, and the journey there and back will take four days. It is very annoying but it cannot be helped I shall cross some of the smaller ranges tomorrow and so shall get some idea of the soil. I had fondly hoped to have made an attempt to reach the highest point of the mountain (not however taking my own men, as they would, I feel sure, have been prostrated, for the rest of the journey) but getting some of the men of Kian. The journey however to the base had to be postponed; a trip to Kinabahu must be a trip of itself, and not as we are, bound for Bungen in the Marudu Bay, several days' journey from here. The cattle I saw grazing on the patana in front were as fine as any I have seen in Borneo. I fancy the climate and fodder must be in a great way the cause. I shall not easily forget the shock of a cold water bath up here: it was very different to the warm water one gets on the coast. The chief who had been out all day came iback in the evening with his wife, both in a high state of ntoxication, at which he seemed very proud. Mr. Saunder s procured some very fair samples of tobacco, but I anticipate he will get better as he journeys on. The natives here appeared to think they would make a fortune out of us in bartering, but they were mistaken, as they got nothing except what I gave the chief as a present. I saw here for the first time a musical instrument resembling a bagpipe which was made out of a pumpkin.

August 8th.—The thermometer was 66. I was glad to make an early start. Our track took us down to the river again, which we crossed several times, and then struck off and ascended the hill facing Kian, passing on our way tobacco gardens. We arrived at last at the bottom of the range that separates this valley from the next, which we slowly ascended. I examined the soil, which appeared very good, and took a sample for analysis, the elevation being 3,000. Higher up I came across a newly-burnt clearing, the soil of which was similar to that I had seen below. Arrived on the ridge 4,700, we found an abandoned clearing from which we obtained a fine view. To the east and adjoining Kinabahu I see fine jungle, but at a high elevation, say from 3,500 and upward, while to the south-east one sees the supports to Kinabahu, as mentioned in the late Mr. Witti's diary, and with fine forest on them. The near ranges are called Siago and Sungei. In front below us are two villages separated by a small valley from each other. They are called Tuan and Tiong and must have sixty houses between them. We appear to be in altogether a different country since we crossed the range. We were not long in arriving at Tuan. We found the inhabitants very suspicious of us. I told them not to be afraid, as we did not intend to hurt them. I don't know that they said anything in reply, but I fancy, when they saw my few weary followers without any sign of a weapon they must have *thought* a lot. I enquired for the headman, but they said there was not one; every man was equal. On my asking for a house they declined to give me one: so we rested under a *jak* tree while I sent some of my men to look for some of their race, viz., Bagows. One was quickly found, and we were soon all comfortably housed, all the inhabitants of the place coming to have a look at the white men. I told Sandy to do a little hartering, as we were out of rice, but as usual the people want more than we are inclined to give. We shall, I think, be better able to do it tomorrow, when they see we are on the point of starting. I noticed jack, lime, and orange trees, all of which appeared to thrive wonderfully well. There are also a good number of wraps of straw on the house-tops, which indicates heads within, but in the house we stopped at I did not see any. The reason of the people here being suspicious is easily accounted for. In general cases we always obtain a guide, and, if we arrive at a strange village, the people know in the course of a minute or so who we are, where we came from, where we are going to, etc., but in this case one of the men knew the way; so it was not necessary to get a guide.

August 9th.—We were delayed till past seven buying rice, the women having, as I anticipated, lowered their terms. Having obtained as much as we could carry, and our guide being ready, we continued our journey, the road taking us down to a small river called the Legan, which we followed for some distance and then ascended a steep hill to a small village on some patana called Kinau D sun. The men being some distance behind I sat down and admired the view. To the south-west I noticed range after range of jungle, but this is often very deceiving. For on steering for the expected ranges you find the eye has caught all the top ridges which generally are uncleared, while below the land is either in a state of cultivation or abandoned. Round about me I find small chena is being felled, the ashes and burnt soil being, I suppose, sufficient to raise a crop of paddy. The stragglers having arrived, we continued our journey, which was incessant ups and downs through chena, and the rain which commenced to fall made the ground very slippery. At one o'clock we arrived at Kapuringan, and here our guide declined to go farther, but luckily we found a man and his wife who were going our way and who acted as guides. We travelled through a good deal of bamboo and then arrived at a large village on the banks of the Yaggo river. The headman was out, but we made ourselves comfortable nevertheless.

August 10th.—It rained all night and in the morning I found our host had not yet arrived. The cocks crow

very early here, and were the means of my waking my men up at half-past four, thinking they had overslept themselves. However, there is nothing like making an early start in these expeditions; so having had our morning meal and procured a guide, we continued our journey, leaving, however, a small present for our "absent friend." We crossed the the river and steered in an ENE direction. Kinabalu, from here, appears very close and very long, the supports standing boldly out. After crossing one or two pretty grass plains we arrived at the outskirts of Danoe Plain, having latterly steered due east. It being 8 o'clock we had our breakfast on the banks of the river and then continued our journey skirting the plain. I should have preferred stopping here last night, but our guides would not come on and there were no others to be had. This plain will, I anticipate, be a large settlement some day, and would be a suitable place for a road from Bungon through the country were one made. The soil on the plain is very rich and paddy, I am informed, is here irrigated in a proper manner. From Danoe we steered due north and crossed a small hill, the soil of which appears excellent, and so I took a sample, the elevation being 2,100. From the top of this hill I was able to continue my survey of Kinabahu, which I am gradually getting round. There appeared to be several thousand acres of land quite close, and which, I am sure, would be found suitable for tea and cinchona, while below some of the land might be found suitable for coffee. On descending on the other side the soil was hardly as good, but igneous rock was plentiful. We travelled along a jungle ridge for two hours and then descended to a small village called Legan and waited for stragglers. Leaving here we passed through some flat land with good soil and jungle till we came to a small river called Uhan, where we rested. From here we passed principally through cheua till we came to a small village on the top of a hill, called Boukud, from which there appeared a good amount of jungle round about. This may possibly be owing to the proximity of Danoe, which ought to supply sufficient rice for the inhabitants round about. The next village we arrived at was Le Manse, and here our guides wanted to stop, stating that Lasas, the place I wanted to reach, was too far off. The people, however, of the village stated it was untrue, so after a short remonstrance with the guides we continued our journey and shortly after arrived at Lasas, better known as Guppo. We unfortunately missed the headman's house, but put up at another farther on. The people here remembered well the late Mr. Witti, he having stopped here on his way through Borneo. The land in the immediate vicinity appears flat, soil good, with a fine, clear river running through it. Towards Kinabahu I see two fine ranges covered with forest, which are named Lalumut and Pinonwentii. It seems strange to me, knowing the pushing nature of the Chinaman that none of his race are to be found inland. The reason, I feel sure, is, no white man, and so no Chinaman. What will, I think, be found the quickest mode of civilizing the natives inland will be :—1st European residents, 2nd a good road, 3rdly Chinese traders and agriculturists. A want I feel myself and which will also apply to them, is a dictionary of the Dusun language.

August 11th.—Started along the banks of the Yang Unnen river shortly after six o'clock, the soil in parts being very rich. On our way I experienced for the first time the "bad bird" nuisance, my guide always coming to a standstill. I persuaded him to go on a little further, and he would be sure to hear a good bird, but it appeared to have no effect on him. After a few moments of thought, in which I fancy blue cloth occupied a conspicuous place, he stated he would act as guide to the village, but could not stop the night. I concealed my sorrow and proceeded, passing the small village of Maranti (700) on our way. Around here jungle appears plentiful and the soil fair. To the N.W. Tinocun hill is to be seen, around which there appears fine jungle. The next village we arrived at was Mituo, and, as it was extremely hot, I accepted the chief's offer to come inside his fine house. He appeared a very pleasant man and remembered the late Mr. Witti when he passed through a year before. He gave me some information about my route and I then started, but not before giving him and his pretty little children some small token of friendship. From here we passed through jungle and cheua till we arrived at the the Kapooikan river, alongside of which there is a village of that name. We found the headman out, but made ourselves comfortable all the time.

August 12th.—We did not get away till close on 7 o'clock —the old story: guides not ready. Our route was not very interesting, as it was principally along the banks of the river. Passing on our right a small village called Kinuntang we then ascended through scrub to Mardli. I was rather disappointed with this place, there being only two small houses, one of which we occupied; but there did not appear much chance of our being able to increase our rice supply. I always like to have two if not three days' rice in hand, as one is then independent and can buy at a reasonable figure; but now, when we get to our next halting-place, Mumus, we shall have to buy at any price. The elevation here is 1,500 feet, and we are shut in with jungle which rises to 3,500 if not more. From here to Mumus takes a whole day, so we are forced to stop, though only 11 o'clock. Timberanokan appears to our west and has therefore a fine eastern aspect, and Tambuyukan, another fine range close to it, near which I expect to pass tomorrow.

August 13th.—We were all ready for our expected early walk by 6 o'clock, but the guides were not, and so we were delayed till seven. Our route led along the ridge of a range behind our house, the soil appearing in parts a light loam, while in others more dark. I took samples of both. We descended after having crossed several ravines to the Tambuyukan river, and while two men were eating their meal I looked for minerals; but I found none, although the place shone with mica. Continuing our journey along the banks of the river I noticed the soil was very fair and free from sand, as is not generally the case. To our west Tambuyukan hill is very distant, the height, I should say, being 5,000 feet. We arrived at Mumus at 12 o'clock, earlier than I anticipated, and, although our guide had told us, Mr. Hatton, the mineralogist of the Company had a house here it turned out to be untrue; his house being a little further on at a place called Kinarum. Our guide maintained he knew the road no farther and the houses around being empty everyone being out at work we were forced to stop where we were. Surely guides are the curse of travelling inland.

August 14th.—The houses had filled during the course of the evening before, and I made arrangements with a man to act as guide to Kinarum at which place we arrived shortly after 9 o'clock, and had the good fortune to find Mr. Hatton in. We stopped the night in his "palatial" residence, my men being able to get a good supply of rice.

Aug. 15th.—Early this morning we started, following an old Sheriff on a buffalo who was going the same way but before going far I discovered he was quite as ignorant of the road as I was, and the only encouragement he could give me was that if we lost our way we would be *all lost together*. This might have been all very well for him but it did not quite suit my arrangements. So I picked out two of my sharpest men, and we soon got on the right track, leaving our friend with his buffalo to follow at leisure. Our route took us over a lot of flat land with good soil on the banks of the Kinarum river and which will I think be very suitable for Chinamen. Leaving the plain country we ascended a range called the Karamendicot, the highest point of which was about 1,500 feet. The timber was very fine, and the soil fair. We travelled through it for 5 hours and then descended again to the Kinarum river and put up at a small village on its banks called Timbangbattu (250). The country round here and to Bungon appears rather sandy. Mr. Saunders however procured a very good leaf of tobacco grown close here.

August 16th.—The pigs having absconded with one of Mr. Saunders's boots we were a little delayed. It was very different travelling to what we had been accustomed to, it being quite flat. The soil however was similar to yesterday, rather sandy. Arrived at Bungon we put up in a Chinaman's house, who I noticed was in the act of dispatching a boat to Kudat containing a good amount of gutta, rubber, rattans, &c., which had been collected principally in the neighbourhood of Kinarum. In conversation with Sheriff Shea the principal man of the place, he told me paddy was the principal product grown and that only in the wet season.

August 17th.—I was rather surprized and annoyed this morning by my men refusing to go any farther. From here it was my intention to cross overland to the

Benkoka river and proceed south, crossing the Sugut and back to Mr. Hatton's station. I warned the men they were breaking their contract with me and that they would obtain no wages, but this appeared to have no effect upon them, for on my return from a stroll I found they had already decamped and taken a short cut home. I heard afterwards that the report of cholera at Benkoka was the reason, but they never mentioned it to me. I made attempts to get men from the headman here, but he told me all the men had left and were working at Kudat, and that my best way would be to go there and procure them. So I obtained a boat and arrived at Kudat in the early morning of the day following.

Sept. 7th.—There is a long gap in my diary, the cause being due to cholera at Kudat and which prevented my taking men inland, but the pest having passed away I was able to collect a few men (the cholera having driven off a lot to Labuan, Brunei, &c.) and proceeded to Kinarum and join my force with that of Mr. Hatton's. On my arrival at Kudat from Bongon, I heard the sad news of Mr. Witti's murder. I little thought when wishing him goodbye inland behind Kimanis I was to be the last white man to see him alive. We started early for Bungon, and would have got there before dark had it not been for the tide being low and we consequently had some difficulty in getting our boat over the bar of the river. Arrived at Bungon we put up in the Chinaman's house and found a letter from Mr. Hatton, saying he had left for the Marudu river, a short distance from here, and to meet him there.

Sept. 8th.—Went over to Sheriff Shea's house to get the goods I had left with him and to obtain a guide. These having been obtained I started for a village called Mendanow. We travelled for some distance over the same flat land as previously experienced and with no sign of cultivation. We passed several small rivers which might be utilized for irrigating this plain and then arrived at a fair-sized village called Ramrow on the banks of the Marudu river. Here I rested and waited for my men, but, as they made no sign of turning up, I pushed on without them, crossing and re-crossing the river several times, then passed through some flat jungle with fair soil, which brought me out at Mendanow. Here I found Mr. Hatton at home, but rather seedy, owing to an attack of fever.

Sept. 9th.—Started up a hill behind our house to S.S.E. up to 900 feet. There was principally chena and poor soil; at 1,150 it improved. I found my stay at Kudat combined with an attack of fever had not improved my walking condition. At 1,900 feet I examined the soil again and found it less sandy, and this continued up to 2,500. The timber was very fine and shewed no signs of wind. In the afternoon I crossed over the river to a ravine in which Mr. Hatton was blasting. I ascended the hill I had noticed in the morning from the opposite side. The soil appeared light and sandy, while below it partook of a more clayey nature with signs of oxide of iron.

September 10th.—The next place we wished to visit was Pampang, farther up the river, and, as we could obtain no guides, we followed its course. Travelling along rivers is very monotonous, as the rough road occupies so much of one's attention. We arrived at our destination, Lomaine, during the course of the evening, and put up at the headman's house. Tomorrow we intend to explore the surrounding hills which completely shut us in. The elevation here is 800 feet. I find several kinds of paddy (hill) are grown here on account of their different flavours, but the most remunerative is a Sarawak paddy called Kalumbuan. It takes 5 months from the time of sowing to be ready for reaping. I purchased a piece of rope made from the bark of the Tumbaran tree, the same as rough coats are made of. I procured a sample to send home. The tree appears quick-growing, rather resembling the Ceara rubber, and seems to thrive in any soil.

September 11th and 12th were spent in exploring this neighbourhood, and we then decided to return to Kinarum and proceed from there to the western face of Kinabahu. We duly arrived at Ramrow, the village I had rested aton my way. I was sorry to hear cholera had broken out at Bungon. This will alter our plans a little. I had my first ride on a buffalo today and have come to the conclusion I prefer walking.

September 13th.—I left early with most of the men, Mr. Hatton paying a hurried visit to Bongon, but will join me in the evening. It was a very warm day, and I was glad when our walk was over. A bath in the river adjoining Timbangbattu refreshed me however.

September 14th.—We were ready to start early but found two of our buffaloes had got away during the night; so we had to wait the whole day. They turned up in the evening, and so we made all the necessary arrangements for the next day.

September 15th.—I am now travelling over the same country as I did a few weeks before. We saw rain coming up, so pushed on and reached Kinarum just as it was beginning, but the river we crossed was impassable for our men, who arrived half-an-hour later, so that it must have been raining heavily farther inland.

September 17th.—Having made preparations the day before, we commenced our journey for our trip towards Kinabahu, steering S. W. The first halt we made was at Kias, where Mr. Burbridge was living and searching for minerals. We waited till our buffaloes arrived and then continued our march, leaving the river behind us and ascending a hill, passing on our way small gardens containing paddy, sugarcane and Indian corn, the soil appearing excellent. From the top of the hill I obtained a splendid view of the surrounding country. To the east I noticed several fine ranges of jungle, which are, I believe, the watersheds of the Paitan river. There I hope to explore in my trip from Kinarum to Benkoka on my return. The Tambuyukan range appears very close and I shall certainly visit this fine range also on my return. The immediate country is mostly chena with fair soil. Here and there some coconut and fruit trees shew signs of a previous settlement, the inhabitants having "moved on." The rain we had experienced in the morning still continued but fortunately there are no more rivers to cross, but it is all the same very uncomfortable walking. Arrived at a small village with two houses, we stopped and put up in one for the night, the rain still continuing.

September 18th.—We left early for Kian, but not the Kian I had previously visited, but one called Kian Gendokud, our direction being S. W. We passed through nothing but chena, but the soil, especially on the flats, appeared very rich. I noticed the remains of several old settlements. It seems strange to me that the people should abandon fertile land. The only reason I can attribute it to is that the weeds and lalang get too troublesome for them and that they therefore prefer to fell new land, which, besides giving them a larger return, is for a year or so pretty free from weeds. This though is a very extravagant habit. The rain today was very heavy and added much to the fatigues of the journey, the roads becoming so slippery. We arrived at our destination on the banks of the Jampassuk during the afternoon, but before descending I obtained a good view of the Abbai and Jampassuk plains as well as the sea. All the country around here is chena, some of which is being felled for the second time.

September 19th.—Leaving this morning we entered on a very different sort of country to that around Kinarum, this being the regular Jampassuk lay of land, consisting of easy undulating hills covered in many instances with fodder grass as high as one's head and in other parts with lalang and chena. Here and there we saw small patches of paddy growing, and it certainly seemed as if anything would grow in this steamy climate. The soil appeared light and sandy, and after last night's rain was of course looking its best. A good view is obtainable here of the country round about, old Kinabahu standing boldly out. The valley we are travelling up is parallel to the one I travelled on my first journey, but to the west. I forgot to mention a pretty little village surrounded with coconuts, which we passed on our way. It is called Mouhabar, and possibly we may stop at it on our way back. We crossed the river twice and found the current very strong, and the black clouds overhead shewed signs of approaching rain. In crossing a stream we were rather horrified to see one of our buffaloes that was carrying rice disappear under the water. Fortunately little damage only was done. Continuing our journey we reached a small village called Tarentedon. From here the road is impracticable for buffaloes, so we unloaded the rice to distribute it to the men, but during the process it rained so heavily that we decided to remain where we were for the night. During the course of the evening the rain stopped, and we obtained a close view of Kinabahu's northern face with the Tambuyukan range on its east. The former

appears, as would be expected, very precipitous, but there appear several smaller and easier ranges beneath. To-morrow I expect a still better view. The people here appear to be a very poor lot and live principally on kiladis. On enquiring about Syap, which is a large village near here, they tell us we cannot even get rice there, should we want it. The paddy in this neighbourhood, it appears, suffers from a grub, which attacks its roots when young, but if the plant gets fairly started it does not suffer. This is the reason these people buy rice from the people of Mumus.

September 20th.—We started early for a village called Padoss, which, we were informed, was nearer to Kian than Syap. The road, certainly, very steep and difficult, and was, I should think, seldom used. From the top of the grass hill we obtained another beautiful view of Kinabahu and the Tambuyukan range. Here, the highest point of the range called Nonahan I. Agaioh, looks fully 5,000 or 6,000 feet, the range being a continuation of Kinabahu. The Dusuns appear to be gradually working their way to the base of the mount, but there is still a large tract of forest in reserve. The smaller ranges of Kinabahu appear to run up to 3,000 and 4,000 feet. So far our journey had been fairly satisfactory, but after this our guide took us through some of the worst country imaginable. Our men, who had got an extra supply of rice to carry, were compelled to go up and down short cuts in the jungle without the smallest trace of a track. I allowed Mr. Hatton to bless the man for some time, and then I gave way as well. The fact of the matter was he had lost his way. We eventually came out some miles distant from the village we intended to get at.

Sept. 21st.—A miserable wet morning and very uninviting for our journey, but we are short of rice and must push on. We hoped to reach Kian today, but, owing to the rain and flooded rivers, we did not even reach Tambuyuan, the village I had previously stopped at. The incessant chena around us would make the journey very uninteresting were it not for the fine view we get occasionally of Kinabahu and surroundings. How we regret we did not take the route via Syap. We shall certainly return that way if we ever reach Kian. While I am writing there are some black clouds in the distance, though we are at present under a scorching sun. Arrived at the river, we found it too swollen to cross; so we put up for the night in an abandoned hut, over which we spread our waterproof sheets and made ourselves as comfortable as we could. After dinner we settled ourselves down to sleep, when the rain commenced, blowing straight in and wetting us, baggage and all. I covered myself up in my rug and waited for daylight, and, as you may imagine, we neither of us had a pleasant sleep.

Sept. 22nd.—We found at daylight the river was more swollen than yesterday, and, as our guide said we would have larger ones to cross later on, we came to the conclusion that we must retrace our steps, as our rice supply would not allow us to wait, neither could we buy any on our way. Our return journey was accomplished quicker than we came. Mouhaban we reached the same night and Upper Kias the following, but at the last place we had to go to bed without any food as a change, having overwalked our men. Mr. Hatton now I remember had a sumptuous feed on Indian corn, for which he was sorry the next day.

Sept. 24th.—I was up and away early to get something to eat at Mr. Beveridge's, and then pushed on for Kinarum and went to bed with a good dose of fever. Though our trip through the Sissio country was short and we did not reach Kinabahu, nevertheless it was very interesting. I was greatly taken with the Tambuyukan range, which, with the country around Kinabahu, must comprize many thousand acres with a general elevation, say from 700 ft. to 4,000 ft., the land as a rule being steep. I forgot to mention that during the journey my aneroid got out of order. This I found most annoying, as it is so important to know the elevation one is travelling at. It was always securely packed, and I can only attribute its defect to dampness.

Sept. 27th.—Our men having to go to Bungon for rice and feeling better I decided to proceed to Kias and join Mr. Beveridge in a trip up Tambuyukau.

Sept 28th.—I arrived at Kias last evening and this morning we made an early start in a S. W. direction, leaving the river after a few hundred yards and commencing a steep ascent with no sign of a road. The soil appeared very good, free of all sandstone, limestone taking its place. The timber was not so fine as I have seen elsewhere. We crossed several ravines in our walk but discovered no water; so when we arrived at the ridge I sent some of the men away to find some for our evening meal, while the others built a leaf hut.

Sept. 29th.—This morning we continued our journey, descending on the other side. It was very steep and rocky; immense boulders of limestone and excellent soil. Descending to a ravine we found a small spring at which we halted to have our breakfast, not knowing whether we would get any farther on. Continuing our journey again we came to a big landslip from which I was able to obtain a good view of the range facing us. That is the one to follow if one wishes to reach the top of Tambuyukan but in my case without an aneroid it is not worth while. Descending again we heard the noise of a rush of water and soon after arrived at a ravine which had a large supply. We could have reached this yesterday if we had known water was to be had. Leaving our men behind us to build leaf huts, Mr. Beveridge and myself proceeded up the next ridge. This same sort of travelling I am sure extends as far as Kinabahu. We ascended as high as 2,500 and then descended well pleased with what I had seen. Planters who come to this country should pay this range a visit. They could grow cocoa, pepper, and Liberian coffee at the lower elevations and tea, cinchona, cardamoms, Coffea Arabica, etc., at the higher. Kias, the place I started from, can be reached in four days from Kudat via Bungon, Timbangbattu and Keroom.

Sept. 30th.—It rained heavily during last night, but our little leaf huts kept us dry. We decided to return by the river, but the big boulders made it very difficult travelling, and much more so when we got into the Kinarum river. Each side of the river was very precipitous, and it was no joke to have to scramble up the sides and walk along to miss some high rapid below. The last one we came to we managed in a different manner, sending our men round with our coats and boots while we swam the distance. We arrived safely at Kias, and Mr. Beveridge at once packed up all his things and we pushed on for Kinarum to meet Mr. Hatton, and then proceed together on the Sugut river trip, as mentioned previously. At Kinarum we found Mr. Hatton was away searching for some supposed birds' nests a short distance off.

October 2nd.—Kinarum is a very warm place, being shut in with jungle, but then it has a splendid bathing-pool, which goes a long way to remedy the heat. Mr. Hatton arrived in the evening very exhausted, after an unsuccessful attempt to find the caves.

October 3rd.—We decided last night that Mr. Beveridge and self should start at once for the Sugut country, but on Mr. Hatton seeing the samples of quartz collected during our trip, one appeared to contain such good traces of copper that he decided to send Mr. Beveridge back and follow up his search. This of course put all my arrangements out as I have only seven men, which are insufficient for the journey I have before me. However Mr. Hatton kindly placed three of his men and some stores at my disposal, so that I was able to make a start during the afternoon for the village of Pomatum, passing on my way through flat chena land with poor soil. Our direction is due east; to the west I noticed a long range of forest close to Tambuyukan and which is called Medallon. It appears to run up to 3,000 or 4,000 ft.

October 4th.—We left Pomatum early, but on arriving at another small village farther on I found one of the men was very bad with fever; so I had to stop and divide his load and send him back. From here our journey was very trying, the hills being very steep and water scarce At a small house in a clearing, I came across some Kudat men who were collecting gutta in the neighbourhood. The jungle we passed through towards the latter-part of the day had some splendid timber. Arrived at Moroli, I put up in the house of Balanting, the headman. In my previous visit to this place I stopped at a house on the opposite range. Here I was shewn a small shrub called Home, the leaves of which closely resemble that of a young cinchona succirubra in appearance. It is used as a dye in the place of indigo. The leaves are boiled and the thread or cloth is immersed in the liquor. The plant they told me was ready for plucking three months after planting.

October 5th.—Balanting offered his services as guide, so we made an early start for Tibebar. The route was picturesque but otherwise not of much interest, as it led along the banks of the Kapooikan river. Later on we branched off and ascended to a miserable little house, in which we put up in for the night.

October 6th.—Our journey this morning continued along the banks of the Kapooikan, and then we ascended through scrub and clearings to a village called Losus. The soil here appeared good, and I took one or two samples of it. The people here are a suspicious lot and think I have come to spy the land for gutta and are therefore very unwilling to give me any information. I had a touch of fever in the evening by way of keeping one's spirits up. I forgot to mention an old chief I meet on the road during the day. He told me there had been a man rushing about the country where I was going to and who had been eating men and women. I asked him why they had not killed him, but he said they were unable to catch him. I then asked if I should have a chance of putting a ball into him, but he stated the man had cleared out and gone in the direction of the Paitan river. I discovered next day that cholera was what the old gentleman had been aiming at.

October 7th.—Started for Tinegas shortly after six o'clock, first crossing the Sugut river and then taking rather a round through jungle and chena, the soil of which appeared good, and arrived at Tinegas about two o'clock. The people appeared glad to see me, they having been visited previously by the late Mr. Witti. The house was a fine large one, containing, I should think, about 20 families. As is usual at this time of the year, the house is nearly empty during the day, all hands being busy in the clearing. Towards evening men and women came trooping in. Most of the evening was spent in buying rice, as our stock is getting low. I happened to open my medicine chest to give one of my men some. I was at once besieged; everybody had something the matter, even little children only a few months old, their mothers stated, were suffering in all sorts of ways. I distributed as much as I could spare, telling them at the same time I would not be responsible if a few of them died before marrying. This they appeared to think must be naturally expected. Sendoon, the chief, appeared a very good fellow. He told me that the Kagasingans, who are a small tribe not far from here and are the only ones given to headhunting in these parts, had taken his country from him. I told him he would have a white man to tell his complaints to shortly at the mouth of the river, at which he seemed very pleased. A Sulu trading boat arrived during the day, having taken about ten days to get here.

October 8th.—I prevailed upon Sendoon to come as guide as far as the next stage, Mellinsom, and so we commenced our journey by climbing a steep hill behind his house and through some extensive clearings which had been just burnt off, the soil of which appeared good, but rather light at the surface. Passing on we came to chena and then a jungle range rising up to 2,000 feet with fine soil and timber. It was rather heavy going, being up hill and down dale incessantly. I had pointed out to me for the first time a small shrub called Lebullyboo, the leaves of which are used as a substitute for quinine. On nearing Millinsom there appeared nothing but chena around us, and I fancy this must have been a large settlement in days gone by. We put up at the house of the principal man named Tuggerging, but as usual every one was out. The house was a very poor one after Tinegas, and it was some time before I laid my traps down, having to search for a spot that was waterproof overhead, experience having taught me caution. Celo Tuggerging came in during the evening and I at once nicknamed him King Cole, as he was a merry old soul. He remembered poor Mr. Witti well.

October 9th.—Tuggerging accompanied us as guide this morning. Around the village I noticed a great number of fruit trees of all descriptions. After a few hours' travelling we got into jungle, fine big timber but mostly surface feeders. The usual ups and downs were the order of the day. To the north and north-east, I observe some fine ranges of forest which I expect to pass through. I noticed that the lower portions are in many instances cleared. Arrived at the Katahanan river, we first saw a party that were bathing in the river, but the instant they saw us coming there was a general stampede, articles of clothing, etc., being all left behind. Passing on we came across the headman and his party, who did not seem very anxious for us to stop, and gave us guides on to the next village. It was not far, but up a tremendous hill, which is always very trying at the end of a day's journey. Our guides pointed to the houses and then left us; so we arrived without the usual introduction. We found the place nearly empty, but picked out the best house and made ourselves comfortable, and only just in time, for it rained heavily, and some stragglers who came in late resembled drowned rats, while their companions were nice and dry. Sibango, the headman, duly arrived, and was very polite, though at the same time rather astonished to see us. He pressed me to take a lot of fruit, and promised guides on the morrow. The people here talk a queer sort of Dusun: my interpreter can only understand it with difficulty.

October 10th.—I was amused this morning, when, upon giving the chief a few yards of cloth, and his wife some needles, he hesitated to take them. I enquired the reason, and it appeared he was under the impression if he took them I would at once want something or ask him to do something in exchange. I soon explained to him it was only a small token of friendship and for the use of his house. The guides being ready we continued our journey, the roads being very slippery and steep. Arrived at a jungle range we travelled along the ridge, there being several small clearings below us on each side. We appeared to be going a good deal out of our way by my compass, but the guides declared this was the only route. Arrived at a small village the guides handed us over to some others, and from here our track was along a small watercourse, bringing us out at a place called Waigan and opposite a house in which three gutta hunters from Bungon were living. They pressed us to stop, which I did, though only twelve o'clock, but then we have a difficult journey tomorrow over the Nipis Nillu range, and besides I have my diary to write up and some clothes to wash.

October 11th.—Made an early start for Raliu, climbing being the order of the day. We first arrived at some chena with the remains of some houses which appeared only recently vacated. Shortly after we entered some fine forest with a fair soil. This range rises to 2,100 and there are several others round about us. I noticed several *young* gutta plants, but the older trees were conspicuous by their absence, they having I fancy caught the eye of the gutta hunter when travelling along this track. At the top of the ridge we found a strong fence, which was put up to keep the people of the village we are going to from entering the one we have left, there being reports of cholera at Benkoka and Bungon. We had a steep descent through high grass to Ralin, there also being a large amount of wild plantain. Arrived below I put up in a small house, and the owners at once went out and brought in large quantities of sugarcane, Indian corn and potatoes. These myself and my men enjoyed, as there was no rice to be had.

October 12th.—Having procured a guide we pushed on for Sonsogon, passing what used to be a large village called Palawayo, but the people have recently "moved on." Our path appeared to take a direct circle, but Dusun paths are generally of this nature. We passed through some good forest which had excellent soil, there being also a fair amount of young gutta trees about the place. Arrived at Sonsogon the people appeared glad to see us and stated if we would stop they would husk some paddy for us during the night, to which I assented, as I feel far from well. This hilly country, combined with my recent attack of fever, is beginning to take effect on me, but I hope to struggle on to the end. These people of the Sonsogon district appear superior in every way to the Dusun, being painfully polite and hospitable. The women also appear to be fairer than the Dusuns. The houses are all boarded with bark. I noticed a good supply of beeswax.

October 13th.—We entered jungle soon after leaving the house, ascending and descending as usual. The soil appeared rich, and I took a sample. Crossed the Nomar and Sonsogon rivers, which gave us our last supply of water for several miles. Later on we spied a house below

us, for which we steered, but had to get over all sorts of barricades which had been put up to keep people out who come from Benkoka. Directly we reached within hailing distance of the house there was a regular stampede: women picked up their children and old men hobbled off as fast as they could go to the jungle. I called to one man and told him we had not come from affected parts, but this was of no avail; so not wishing to alarm them more I told my men to return to our track again. Here we spied another Dusun just on the point of bolting, but we caught him and had a regular explanation, after which he pointed us out a small house in which we put up. Most of the people around Bungon and Benkoka, directly the cholera broke out, made a rush for the hills and put up a small hut and planted potatoes, waiting for the pest to disappear. One of my men who loitered behind has not arrived, but I have no doubt he will find his way allright, as I make it a rule to always throw branches across all but the *right* road.

October 14th.—Continued our journey along a buffalo track descending to the Benkoka river. Here I discovered we were making a mistake. One of my men had told me the mouth of the Benkoka is called Bungon. I now found on close inquiry such was not the case, so instead of crossing the river I followed its course, and soon found a track, which I followed, but unfortunately came across no sign of a house, and, as it was getting late and rain had commenced, I halted, and had a small leaf hut made, while some men went on to see if they could find any signs of life and get something to eat. This they were lucky enough to find, and came back with some potatoes, but it was too late to think of trying to find it again. It rained heavily all night and the house leaked like a sieve, causing the man who carried my rug to look rather glum at the addition added to it in the night.

October 15th.—My men had told me over night that two guides were coming in the morning, and they duly arrived. It appeared we were a little off our track and had to retrace our steps. The jungle we passed through was very fine, while to the E. and N. E. it looks very extensive, and, if I was well enough, I would certainly pay it a visit. Leaving the jungle we got again into chena and through some clearings descending to the village of Ebong, Headman Sembilam, and put up in a fine house on the banks of the Benkoka. The people seemed rather astonished to see us and were as usual alarmed about cholera. When the headman came in I told him I was ill and could not walk and that he must give me two boats to take my men and myself down the river. First he said he had none and then he said the river was only practicable for a short distance. I told him in that case I must stop in his house till my men went down the river and got a boat for me. The lost man we found had passed through only a few hours before us; so I sent after and brought him back.

Oct. 16th.—When the chief saw I was fully determined to stop and was collecting my remaining stores together, he came forward and offered me the two boats for a stage, at which place I could get others in the same way. So I was soon ready and being paddled down the river, and in this manner I reached a village not far from the mouth called Rutas. Here I tried hard to get a boat to take us all to Kudat, and, when the arrangements were completed, a boat turned up with rice, &c., for us from Kudat, which we most likely would have missed had it been night. I wished if possible to travel all night, but on getting outside the river I found the surf so high that we had to put back to shore, the soft sand being my bed for the night. I was rather astonished when about two o'clock in the morning I opened my eyes and saw a star which looked rather queer. I rubbed my eyes and thought perhaps the fever I had on me must have something to do with it, but calmly considering the question again I arrived at the conclusion that it must be a comet, which proved to be the case.

April 18th.—We started very early, although the weather did not look very bright, and arrived at Kudat during the course of the day, which ended my journey. I remained here a week or so and was soon allright.

I paid a hurried visit to Selam and then to Singapore. At the latter place I spent a very pleasant three weeks. I accompanied Mr. Watson to Johore and saw the Maharajah's gardens, which were all looking very well. Mr. Bailey's estate planted with cocoa, Liberian coffee, sago, nutmegs and a host of other products, could not be looking better, and reflects great credit on him. Tapioca planters are, I believe, having a bad time of it, prices being bad and disease (caterpillars) prevalent.

Selam, Jan. 17th, 1883.—North Borneo is just now like a beehive, every one being very busy with his department. Mr. Mann, who, (I was glad to see) saw a good deal of the country in a short time—the Tambuyukan range included—and I hope went away pleased with his trip. Mr. Saunders has returned here, and a large tobacco plantation is to be started shortly by a China firm, I think. Town lots at Sandakan are fetching high prices and many are regretting the chance they have lost. Messrs. de Lissa and Saxe have commenced their sugar enterprize, and others are on the point of being commenced. Chinese labour can now be obtained direct for $8 per mensem, but this will be lower after a trip or more of them have arrived. Just before leaving Kudat a very good sample of coal was shewn me and it was stated that a large quantity existed. Mr. Hatton is at present travelling between here and the Kuinamatangan river. Resthouses have now been started both at Sandakan and Kudat and appear to be always full. The first paper printed in North Borneo is to appear shortly, to be called. *The North Borneo Herald and Official Gazette*, and will I fancy resemble in a great way that of Ceylon, only including news from the different stations, and this is what is greatly required. Selam is going steadily ahead. Some of the land applied for will I fancy be only a short distance from here. The plants we have put out are coming on very well, the Liberian coffee beating all records I have seen in Ceylon for its age. What we have either put out or in the course of being put out are tea (Assam), cocoa (red and yellow kind), cardamoms (Malabar), and coffee (Arabica, Coorg, and Java), sugar palms, African palms, pepper, allspice, cloves, cinnamon, gambier, sugar (six Mauritius varieties), indigo, sago, tobacco (Havana), cotton bush, aloe, Manila hemp trees, citronella grass, jak trees, sapan, ilangilang, shave tree, albizzia, and didap, and I also intend to add a large number of varieties of the rubbers and guttas of Borneo.—Yours faithfully, L. B. VON DONOP.

P. S.—Ladies are beginning to come to Sandakan, and more I am informed are expected. Certainly the rosy cheeks of the children are good advertisements for its healthiness.

NEW PRODUCTS IN THE LOWCOUNTRY OF CEYLON.

General Report—Weather—Coffee Blossom—Cocoa—Tea—Caterpillars—Weeding.

From February to 6th March 1883.

Weather.—We had rain on the 2nd and 4th inst. an again on the 12th and 13th, but very light, so that this month has maintained its normal character as the driest of the year.

On the 6th and 7th, a pretty heavy blossom was out on the coffee, and now all the trees not denuded of leaves by the *H. V.* have as much crop as they can carry. The trees made a start of growth early in the month, but the drought has stopped it in mid-career, and now many of the trees are drooping. The growth ran chiefly to suckers rather than to fruit-bearing wood.

The *Cocoa* trees have been gradually getting over the effects of the storm at the end of December, but many of the larger trees still look bare to windward, and the afternoon winds that still continue are against them. Cocoa however seems to feel the drought less than Liberian coffee, and the smaller trees especially continue to grow as if they enjoyed it. The cocoanurseries are a serious difficulty this weather: even when carefully shaded the dry atmosphere sucks the moisture out of the light soil in the baskets in a few hours, and the young plant dies at once when the roots dry. These the white ants find wherever they may be placed, and destroy them as soon as they come up, so that fresh seed has to put down continually not in extending the nurseries but in keeping them up.

I have been unfortunate in the season of forming a tea nursery, as the shading and watering is a serious expense,

but the plants are coming forward pretty well, at least to my inexperienced eye.

The drought told earliest on the *Nutmeg* nursery, The beds are kept well shaded so that no sun directly reaches the plants, yet two daily waterings will not keep them from drooping. The cardamoms stood out longer, but they too are now looking seedy, and require water, though two feet high and partially shaded by standing trees. Hitherto the vanilla vines seem to enjoy all the sun they get, and still grow vigorously.

The other day I discoved the common green caterpillar preying on the leaves of a young coffee field in thousands. I have known this insect for forty years, and never saw it touch coffee before. I had a gang of boys for two days at work, picking and killing.

I have suspended weeding till rain comes. Indeed it could be safely suspended for a couple of months, but for one weed that would be called an annual elsewhere, but is a monthly here. It is a grass, that sheds its seeds within a month of its appearance above ground, and grows as freely in dry as in wet weather. It produces a very large number of very minute seeds that are carried everywhere by the wind, and if left to propagate freely the land would be a good pasture field in six months.

Speaking of weeds, I knew an estate, well nigh thirty years ago, that had been in bearing twelve years, and in no one of those years did the crop cover the expenditure of its year. The proprietor did not follow the usual practice of those days in such cases, namely, making over the estate to his agents for one-tenth of what it had cost him; he merely changed his agent. The very first year of the new management gave him a profit of several hundreds, and the second nearer £4,000 than £3,000. This change in the character of the estate was due to thorough weeding and pruning. When the philo-weedists can point out a clean estate that improved its bearing by letting it get into weeds, then they may hope to convert some of those who believe in the now common practice, that took so long a time to take root, but is now too firmly established, to be eradicated by anything short of unquestionable facts; certainly never by loose, speculative theories. It may be that coffee planting is a doomed industry in Ceylon. If so, it will not be saved by resucitating old systems, tried long ago, condemned and abandoned for good and sufficient reasons. Our side rests on a theory, as old as agriculture itself, and is only questioned from time to time by those who practically failed in mastering the ever-present enemy of the cultivator. When the garden of the sluggard gets overrun, he suddenly discovers that weeds do no harm, and when it gets worse he rises to the sublime absurdity of declaring that weeds do good in cultivated land. "The grand old man" may not be much of a practical agriculturist, but every one owns him a fine intellect. In one of his speeches he told his audience that every thing that grew on cultivated land, besides the cultivated plant, was a weed, and every weed was a thief and a robber. Hamlet, in complaining of the state of affairs in the court of Denmark, says :—

"Fie on't, fie ! 'tis an unweeded garden,
That grows to seed."

—the nastiest thing he could think of.

We live, Mr. Editor, in a great age. Not only is patient, scientific investigation giving us day by day greater power over nature, but we have among us some gifted brethren, who communicate to us the will and ways of nature's God without the toil and trouble of observing facts, or forcing nature by special experiments. One of these great ones is he who has from his inner consciousness evolved the great announcement, that weeds are the choicest gift that a beneficent creator has bestowed on the cultivator of coffee. The original curse referred merely to thorns and thistles, but the ageratum, the spinous needle, and the pasture grasses, are neither thorns nor thistles, and to the incessant war carried on against those precious gifts of nature we owe the terrible visitation that has ruined our once flourishing industry and carried sorrow and suffering to thousands in its train. Had this prophet declared his mission earlier, Ceylon might have *retrenched* the salary of Marshall Ward. The remedy for all the ills the planter suffers is to let his weeds grow ! !

EXPORT TRADE OF MADAGASCAR.

A member of the Madagascar Embassy has supplied the following interesting information to the *Chamber of Commerce Journal* :—

The next important article of export from Madagascar is caoutchouc or india-rubber. The caoutchouc is procured both from a tree and from a vine, but all that I have seen on the east coast of Madagascar is taken from a vine, and if the india-rubber tree is found in Madagascar it is only on the west coast. It is not very many years since the natives were first taught that the India-rubber vine was such a valuable plant. It is true the children would collect the the juice of the vine and with the juice of a lemon coagulate it, but about fifteen years ago foreigners first taught them the value of it, and it is, now an important occupation of those natives who are of a rough and rambling character to go out into the wood to collect it. * * * *

A party of five or six men is formed, each having an axe and a bottle of sulphuric acid and as much rice as he can carry. They are also provided with a few cooking pots, and of late years they generally take with them a gun by which means they can procure themselves food. These men strike into the forest until they find traces of the vine, then they camp and set to work to cut the vines down. These vines are perhaps six inches in diameter at their roots and taper off as they climb round the trees of the forest, forming one entangled mass. The Malagasy climb the trees and cut every branch that can be found, nor do they spare even the roots of the plant. These vines are cut into pieces two feet long, and placed on end in a trough of bamboo out of which the milky like juice is conducted to an iron pot. A few drops of sulphuric acid immediately converts the juice into a curd, which becomes the indiarubber of commerce. It will be noticed that the Madagascar indiarubber of commerce is in balls, just as it is made in these two and four-gallon iron cooking pots. The difference in the quality of Indiarubber depends upon the soil, and also upon the period of ripeness at which the vine is cut. Ripe old vines that are found in the virgin forests of the north-east of Madagascar produce the indiarubber known as the "best piuk." Indiarubber is bought from the natives now at as much as 10d and 1s per lb., though five years ago they sold it at 6d. It undergoes a shrinkage of 20 to 30 per cent. in weight, however, before it arrives in London.

Another valuable export from Madagascar is "*Gum Animi*," the gum of the copal tree. There are two chief qualities found in the north-east of the island, the white and the red, the former being by far the better of the two. It is not the deposit from year to year which we see in our markets, but the ancient deposits which have fallen from the trees years and years ago, and which the natives dig for. When they discover a forest of copaliers they do not look up at the trees for the gum, but they immediately dig for it, and I have seen pieces of gum of 8 or 10 lbs. weight found underneath deposits of earth of several inches in thickness. Gum is bought from the natives at 5d per lb.

Wax from Madagascar is beginning to be an important article of export, and I have quite recently heard that the quality is very good. It is a noticeable fact that the honey of Madagascar is of a greenish tint and thus different to that of most other countries; there is also a poisonous honey in the island, but the wax as far as I am aware, is the same as anywhere else. It fetches about 5d a lb. in Madagascar.

It is not probable that any Madagascar rice ever comes to England, but it is none the less an important item of British commerce, as a great deal is yearly shipped to the British colony of Mauritius.

Coffee and Sugar growing are to be the great in-

dustries of the future, and they have already made a considerable start. With reference to the coffee, I do not suppose Englishmen ever know that Madagascar coffee is in the English market, and the reason is, that it is of such a superior quality that I should not be surprized if it is being sold under a famous name. There is every reason to believe that the Madagascar coffee will compare in quality with the best coffees of the world. Many planters have made great mistakes in planting coffee on these a shore, but it the lands 50 or 60 miles from the east coast were chosen, which lands are about 1,000 feet above sea level, then I can say our planters will have the finest coffee that can be produced.

In regard to sugar—this is an industry which must be carried on by very large capitalists. I am able to give any reliable details for the information of information of those who might think of such investments. I can say, however, that two or three sugar mills are now at work at Madagascar, and moreover, that the soil of the island is all that can be desired for the cultivation of the sugar cane.

The rearing of the silkworm is an occupation particularly suitable to the women and children of Madagascar. That already much is done in this is evident from the beautiful silk *lambas*, the native costume of the Malagasy, which are all spun by hand from Madagascar silk; but thus far no one has commenced buying up silk cocoons for export—a branch of commerce which would immediately increase ten-fold the amount produced.

I will refer lastly to an article of commerce largely shipped from Madagascar, viz., *Rofia fibre*, or the inner skin of the leaf of the Rofia palm. This fibre is stripped off from the under side of the leaf of the palm in the same manner as one can strip off the inner fibre of a pea-pod; in fact, it is very similar in appearance, only that of course it is two or three feet in length. It is dried in the sun, and woven by the natives into what is known in England as grass-cloth; it also serves the natives for all purposes for which twine or string are required.

Seeing so many bales of this fibre shipped to England I made a point of inquiring whether it might not be used for working up into some fabric, but I find that its sole use for florists to tie up flowers. A London merchant informed me last week that the market is at present overstocked with this commodity.

To say a word on the *Flora* of Madagascar, I may remark that some of the principal florists in London are annually exporting from Madagascar the choicest specimens of *Orchids* which grace English conservatories.

I might mention that Madagascar produces maize corn, that even wheat is grown by the natives in the interior, that tortoiseshell is largely collected on the coast, that, in fact there are scores of industries for the enterprizing foreigner.

A. Tacchi.

Ambasadaoranny Mpanjakany Madagascar, London, December 21st, 1882.

PLANTING ON THE HILLS OF CEYLON.

DETERIORATION OF INDIAN TEA—POROUS LEAD—INSECT RORERS OF TEA CHESTS—WOOD FOR TEA CHESTS—ACTION OF THE CEYLON CLIMATE ON TEA—THICKER LEAD NEEDED FOR PACKING—AUTOMATIC FRUIT EVAPORATOR.

Lindula: March 16.

Mr. Cameron (an Assam tea planter) arrived just in time to be consulted about a a very important article in the *Indigo Planters' Gazette* on the admitted deterioration in recent years of Indian tea in "staying" or keeping power. Afterdiscussing under-firing as a possible cause, and while admitting the necessity of economy, the writer alluded to expresses his fears that in regard to the lead used for lining boxes a desire to save expenditure may have been carried too far. To quote:—"Our attention has more than once been called to the condition of tea samples carefully leaded up for future reference, and we must say that had it occurred on one or two occasions only, we should not have paid so much attention to it; but we have seen out of 20 or 30 samples carefully leaded up for comparison, the following season not more than 6 or 8 turned out in anything approaching good condition. To what could the deterioration be due, was naturally asked, to improper leading? to improper firing? or to what? And after carefully weighing the matter and looking at the samples, we were forced to come to the conclusion that the lead used was too thin or to a certain extent porous. This conclusion that the lead, used was too thin, was forced upon us by the fact that the same samples put up in double lead were in good condition, and we trust that this is a matter to which agents will look. It would be interesting if our Calcutta firms would take this matter up, and if possible, ascertain the difference in the quality of the lead now supplied and that used years ago. We imagine that firms such as Betts & Co., and other well-known firms still supply brands something of the same quality as in former years, but we think it more than likely that many other brands that can be bought cheaper, have the lead simply rolled out thinner, and that the weight of the lead supplied to do the same amount of work at a less cost, is considerably less than that of the first brands in the market. We do not by any means say that this is the case, but it is a point which can be easily solved by those interested in tea matters; and we venture to think it is a point which ought not to be lost sight of. The tea lead used in a China chest is, so far as our knowledge goes, considerably heavier than that used for the same sized Indian package. Although to appearance less in size, and yet containing the same amount of tea, we venture to think the difference principally lies in the rough heavy wooden box used for Indian tea" Mr. Cameron tells me that in the early days of Indian tea planting the weight of the lead used was 7 ounces, or a little under ½ lb., per square foot. The lead now used has been reduced in weight to 5 ounces per foot, and of this lead 6 lb. will generally be required for a chest running from 80 lb. to 120 lb. of tea, with 3½ lb. for half-chests. There is a certain economy, therefore, in packing in full chests, which answer for the London market, half-chests being in request in Australia and America. Of course the thinner the tea lead is, the more danger there is of its tearing or getting pierced; but, with reference to the suggestion of porosity, we asked if there was any suspicion of the possible adulteration of the lead with any other substance. The answer was in the negative, but practical proof was adduced that an insect which could bore the timber of which a tea chest was made was able also *to bore through the lead*. So that insect-haunted wood, or timber likely or known to be liable to insect attacks, should be avoided as carefully as those possessing chemical qualities calculated to corrode the lead. Mr. Cameron seemed impressed by the question of the insufficient thickness of the tea lead now, used, and stated that in his own experience in Ceylon he had been much disappointed at the end of six months to find specimens of tea which he had wrapped up in a fold of lead and then covered with paper, and which had been kept in a closed almirah, out of condition. Of course our hot damp

climate in Ceylon is especially inimical to such an article as tea, and the sooner prepared tea is exported the better; but this question of the sufficient thickness of the sheet lead used is too important not to receive immediate and careful attention. A series of experiments should be instituted to set the question at rest. The saving of 2-7ths of the lead used in packing may be dearly purchased if our teas get the reputation of not keeping well,—or not so well as China teas.

I had also just received (all the way from America) in time to shew Mr. Cameron, a representation and description of "THE LATEST IMROVED AUTOMATIC FRUIT EVAPORATOR," patented by McFarland & Wilt of Philadelphia. We were all amused to find that—furnace below, arrangement of trays above, chimney &c.—we were looking at a very close likeness of a tea drier: a gigantic "sirocco," in fact. I wrote of the ten trays (not the *tin* trays as the printers made it) of our improved Jackson's drier (which is doing excellent work); but the fruit evaporator, intended to prepare apples, peaches, &c., for export, has, we should say, from the picture, thrice ten trays fitted into it. Our tea driers are intended to expel *all* moisture: the principle, therefore, is that of the kiln or oven. But the fruit evaporator, although requiring so high a temperature as 212 to 240 degrees, requires also that the air in which the fruit is evaporated should be saturated with moisture. It is contemplated that fruit should come out of the evaporation with 12 per cent of water in it. In this state it is said it can be put by in a dark closet and preserved indefinitely; or better still put up in boxes lined with paper and kept in a cool place. It might be worth while importing one of these machines for the evaporation of mangoes, pineapples &c. But we have no doubt it could be utilized as a tea drier. We shall read the description carefully and let our readers know more about the evaporator, the prices of which (minus the patented hood, which is a feature in Jackson's drier) are from $130 for 24 inch tray size to $600 for 60 inch tray size: say from R300 to R1,300.

March 17th.

I narrowly missed seeing an American fruit evaporator in operation in Australia, a Mr. Pulleine having introduced it and having obtained prizes for fruit prepared by its means. It is like and yet unlike the tea drier. The wire net trays in the case of the latter are pushed into a framework, and when the leaf in the bottom tray is dry (in about 15 minutes) the tray is taken out, refilled, and inserted at the top, the trays coming gradually a step down until that which went in at the top ends at the bottom. In the case of the evaporator, the rims of the trays form the walls of a "tower," which ultimately reaches to a second story, the stove being in a cellar. A tray full of fruit is put over the heat for from 5 to 15 minutes; it is then hoisted by machinery to make room for another below, and this process goes on until the tray first put in and its successors reach and deposit their prepared fruit on the upper loft. In the fruit curing it is of importance that the moisture expelled from below should pass through the successive layers, for the object is not wholly to dry the fruit, but so partially to cook it, that it will keep well. In the case of the tea leaf, of course, the object is to expel every trace of moisture, so every tray is finished off at the bottom in almost immediate contact, a metal plate only intervening, with a heat 280°. In both cases there are two sections of trays, there being a division down the middle. But while in each section of the evaporator there are a score of trays there are but five in each section of Jackson's Dryer. Each of the ten trays has a drying surface of 2 8″ by 2′ 9″ or 7′ 4″ square, a total drying surface of 73″ 4″, which is capable of converting 60 lb. of green leaf into 15 lb. of dry in 15 minutes. One of the great defects apparent in Mr. Shand's machine is that it has only one surface, instead of ten or any number which can be secured in the drier or the evaporator. This and the slowness of the drying process as well as the necessity of employing two heating agents (steam as well as fire) instead of one, seem to militate against its extensive use in tea-drying, however useful it may be for preparing cocoa and perhaps cinchona bark. To Mr. Shand's statement that surface can be increased at will, the obvious answer is that horizontal space may be so increased as to place the leaf beyond the reach of the coolies who are manipulating it. Cannot Mr. Shand dispense with steam and adopt tiers of wire gauze trays? But then would arise the question of invasion of patents. When the model arrives and is tried, I will be able to judge and report.

As regards the American Evaporator, the apples prepared by its means are pared and cores taken out by a machine which is sold by the same firm. It is claimed for the evaporator that it is equally useful for the preparation of vegetables, in which case our Yankee cousins might send us the material for "squash pie." In one of the testimonials, we observe that "corn" (maize cobs, of course) was one of the articles subjected to the process of evaporation. We quote a portion of the pamphlet which describes the mode in which the minimum of fuel is made to produce the maximum of heat:—

To obviate this excessive consumption of fuel, and in consequence, to render the drying more uniform and perfect, it becomes necessary to provide some means of increasing the draft through the drying flue; and to do this cheaply, effectively and conveniently, we construct the apparatus as follows: Over the stack of trays or over the flue we locate a hood, the lower mouth of which may be made of the proper size to envelope the upper extremity of the stack, and connect the upper mouth with the chimney. This chimney is supported above the position of the stack of trays, which stack, as it is gradually increased in height, approaches the mouth of the chimney This arrangement leaves a clear space beneath the chimney for manipulation of the trays, and the chimney is not supported upon any casing for the trays such as immediately surrounds them in previous forms of driers and prevents immediate access to them.

From the heater the smoke pipe is carried up into the chimney just above the hood, and out at the top of the chimney, or, at least, up into the region of the top. To secure the best advantages, this smoke-pipe should be about centrally located within the chimney, and it should be so arranged as not to interfere with the convenient workings of the drier.

From this arrangement it will appear that the heat in the smoke-pipe, which would otherwise be wasted, will be imparted to the moisture-charged air above the drier, and this, in turn, will have a greater tendency to rise and pass off through the chimney, including a more rapid flow of air through the drying-flue, in accordance with well-known principles of pneumatics. The desired increased air-draft is thus economically produced, and the more thorough and uniform drying accomplished. By increasing the draft in this manner—that is, after the air leaves the contents of the trays—the condensation of moisture upon the top tray is obviated, and leaves the fruit perfectly cured, from the fact that it has been dried in the least possible time, without scorching, and the natural flavour retained.

Around that part of pipe between the first floor and its connection with the chimney, we place a jacket, the purpose of which is to confine the heat which would otherwise be radiated therefrom, and to conduct this to the chimney also, thereby aiding the draft within the air-flue, and at the same time excluding the heat from the work-rooms, which are upon the first and second floors.

Around the hood is a canvas or other flexible curtain, hanging down sufficiently far to envelope some of the

upper trays and to exclude the air, which would otherwise enter the hood from the outside of the stack.

To remove a tray from the top, the curtain may be easily drawn out of the way, and will immediately resume its place after the tray is detached from the stack. Since the hood remains stationary, the curtain forms a convenient prolongation thereof, useful at such times as before the stack reaches its ultimate height; and inasmuch as the curtain will immediately resume its proper place after having been disarranged, but little fresh air can enter to cool and check the draft through the stack. While green tea leaves are dried to one-fourth their weight, one-sixth seems a good return in the case of apples. We learn that the French distillers are using large quantities of dried apples for the manufacture of brandy! The following succint account of the evaporater will give our readers a clear idea of the main principles employed, and experts can judge whether what answers for evaporating soft fruits and vegetables could not easily be adapted to the purpose of drying tea leaves :—

Extract from Peninsular News and Advertiser, Milford, Delaware, May 25th; 1877 :—

"The Automatic Fruit Evaporator."—This new candidate for the favor of the fruit growers, has been set up and is now in operation in this town. We have inspected it closely, and observed it carefully, and are inclined to the opinion that it *meets a long felt want*; first, because of the excellent work it does on the *true evaporating principle* and second, because of the low cost of the machine. It consists essentially of a series of trays, resting one upon the other, and forming a tight evaporating tower through which the heat passes from a well-designed and constructeh furnace at the bottom.

The furnace appears to be a perfect piece of mechanism, and generates the heat in an economical manner. The trays are all entered at the bottom, filled with the green fruit, and the pile is easily and evenly raised by a crane power turned by a crank, so that even when full the whole pile is easily lifted and the fresh tray slid in over the heat box on an iron railway. When the trays are all full those first entered are at the top of the pile and are cured ready to be removed and the tray filled and slid in at the bottom to start with its second load through the machine. It is *well constructed, works admirably and appears to be a great success.*

The points most admirably covered by it are :—

1st. The true *evaporating principle* of a rising column of heated air passing throughthe trays in its progress upward.

2nd. Economy in running.

3rd. Moderate cost of the machine.

4th. *Great capacity and perfect distribution of heat over all parts of the fruit trays.*

Cinchona Bark Harvesting.

20th March.

As I write, a cooly brings a parcel and the following interesting note regarding the harvesting of cinchona bark :—

"Dimbula, 20th March.—In the *Observer* of 13th I see a paragraph about harvesting cinchona and 'shaving extraordinary' by a Dolosbage planter. As you take a deep interest in all our new and old products, I send you our cinchona account book, which you can at your leisure look over, and compare notes, and return at your convenience : it may interest you, and beats your Dolesbage friend's shaving to sticks. We got as much in as 324, 337, 368 and 404 pounds of wet bark per cooly on some days in July, our average on the whole being 244 lb per man.

"The *totals* are brought down daily: you will see at a glance the number of men daily, the quantity of work each man did, &c., &c. 149 men shaved 36,473 lb from 19,853 trees, giving approximately, 1·81 lb of wet bark per tree. The quantities alter at different times, as you will see from the different shavings. We only kept in *this* book the number of men for the shaving process : in taking the quill, bark &c. from the sickly trees we did not keep the account in the same way.

"We shaved in the wet weather, and that may to some extent account for the larger quantity of bark brought in on some days.

"I hope the heavy rains we have been getting won't damage our blossoms. They have been very fairly good where we have good wood, and we are all now in *need* of a decent crop."

Cinchona bark as a general rule dries down to about 33⅓ per cent of its weight as taken from the tree, but, as the shaving in this case was performed in wet weather, let us adopt 30 per cent for marketable bark. In that case the maximum of 404 lb. would give as its equivalent somewhat over 120 lb., while the average of 244¾ would give about 73 lb., and the average of wet bark per tree 1·81 lb. may be taken to represent a little over ½ lb. of dry bark. These are certainly very satisfactory results as to quantity, and we trust the prices realized will leave a good profit to the owners of the 19,853 trees operated on.

21st March.

I have watched with much interest the progress of some luxuriaut groves nf cinchona, calculated to remind me of those in which I once took such pride, but the larger portion of the trees of which succumbed in the to third the fifth year from planting out. Three months ago, I hoped that root disease and stem canker might not find access to the groves alluded to. But the inevitable must be, and one-third of the trees are in the course of uprootal. As in our own case, so in this, of course the bark will be profitably utilized, but it is hard to see trees on whose comparaative permanency planters have relied to compensate them for disappointments with coffee, thus "dying off." As in all previous cases, the vast bulk of the delicate trees are officinalis. Succirubra, although not exempt, is by no means so liable to discase, while the robust hybrids resist adverse influences best of all, although I have heard of even a few of these giving way. I believe I may add that where the stem canker has now appeared with such fatal effect the Australian blue gums have not suffered to any appreciable extent. We may, therefore, possibly, be able finally to dismiss the idea that the eucalypts are sources of infection : they simply suffer intensely in cold, wet, exposed situations. In the course of my walk I saw calisayas flourishing equally with succirubras and hybrids in the subsoil by the side of the cart road, and it seemed as if the amount of shade from forest left standing above the road was beneficial. Having heard of the success of a rather extensive plot of calisayas planted under tree shade, I diverged from the main road to have a look at the experiment. Most of the forest trees which originally gave shade now stand up naked skeletons, such as the traveller in Australia is too familiar with as he passes through forests of "ringed" trees, over which the fire ash passed. At a distance from the forest which is still standing there was a fine group of trees *on the top of a knoll.* Down the sides of this knoll the trees were in all stages of decay. On the top of a larger knoll, sheltered from the north-east winds by the standing forest, there was a really fine expanse of flourishing calisayas; but decay appeared as we got down and to the outskirts. The experience here with calisayas is that which is general with officinalis; but the exceptions are such as to set rule at defiance. In damp ravines, it seems useless to attempt to grow cinchonas, and yet I have seen isolated plants flourishing with their feet permanently wet. I have in close juxtaposition two fine hill slopes. On one nearly every tree has disappeared from the top portion, while a fine group survives at the base. In the other case the very reverse results have taken place. No doubt free soil, even if gravelly, is favourable for these trees, but even in such soil they do not always succeed. In some cases they resist strong wind, while in others they are blown out of ex

istence. The most perfect surface draining rarely does good where plants have shewn signs of distress, and yet the taproots of tea plants seem capable of fitting stiff, damp clays for the successful growth of cinchonas. I have much faith in tea on its own account and as a forerunner of cinchona. Indeed our present system is to put in the two plants together. If the cinchonas refuse to grow, we have the tea, which, practically, grows everywhere. I had the old question put to me this morning as to diminished flush at these high altitudes. "Well," I said, "if we only get 500 lb. per acre against 700 in the low-country, there is the compensation of a perfectly salubrious climate." "It is certainly one of the healthiest in the world, as my experience with a large family of children proves," was the response.—From the cinchona account book sent to me yesterday, I take the following details of the earliest experiment with succirubra in this district:—2¾ acres of ———— estate were planted with succirubra in 1864-65. In 1874, that is 10 years after planting, 7,057 lb. of dry bark "gross weight" were obtained from ⅞rds of the original clearing which was coppiced. In 1878 the remaining ⅛rd was coppiced, and 6,457 lb. net of dry bark obtained. In 1879 the ⅞rds of original clearing coppiced in 1874, was cut out, (rooted out, no doubt,) and the dry bark obtained from stems, stumps, roots, branches, &c., amounted to ... ... 13,048 lb.

Add as above 7,057 + 6,457 13,514 ,,

Total ... 26,562 ,,

while the ⅛rd coppiced in 1878 seems to have been still to the fore. At R1 per lb. all round this would give R26,562, or, if the ⅛rd had been rooted out, say R30,000 in 1879 from 2¾ths acres planted in 1864—15 years. This would be at the rate of 9,660 lb. and R10,900 per acre. The ground is, I believe planted again, while a 16-acre field of flourishing succirubra has been added. From that field was obtained the large amounts of shaved bark noticed in my letter of yesterday.

TREE-PLANTING.—At the recent American Forestry Congress held at Montreal, Professor Hough read a paper on "Tree Planting by Railway Companies." In introducing his paper he said that there being in the United States about 100,000 miles of railway, the advisability of tree planting by railway companies for construction and maintenance was an important question, 2,000 to 3,000, and even 3,500, ties (sleepers) being used per mile. The average duration of ties is from five to eight years, consequently from 30,000,000 to 50,000,000 a year will be required for 100,000 miles of railway. Putting 500 ties as the product of an acre of woodland, from 60,000 to 100,000 acres will have to be cut every year, and as it takes thirty years for a tree to grow to the right size, the railway will require from 2,000,000 to 3,000,000 acres—or 3,125 to 4,687 square miles of forest to keep up the supply. At this rate, the *Railway Review* says, there should be twenty-five acres for each mile of road, involving an investment of £100 in land per mile—a wise investment, giving the railways an independent supply of ties. He seated that wood fuel is being superseded by coal, and wooden bridges by stone or iron. In Europe, wood in railway structures is very rare, and for ties, mineral substances will be much dearer than wood for some time. The professor concluded his paper with some references to the necessity of planting trees to hold embankments together by their roots, and alder and willow to prevent erosion of streams and the various kinds proper to plant for different purposes and in different localities; also the prevention of snow-blocks by having trees along the railway tracks.—*Knowledge.*

SILK-WORM'S EGGS.—The Government of India have received intimation of the despatch of silk-worms eggs from Dehra Dun for experimental rearing in Madras as desired by the Madras Government. But as there is no reason to believe that they were exposed to the influence of warm weather, which renders them liable to hatch a further supply of the eggs, packed in ice, has been despatched. This supply is from Kashmir, and is of the univoltine variety. With them has also been included a small quantity of eggs just received from China.—*Madras Times.*

THE ACTION OF COFFEE.—Dr. Guimaraes, of Rio de Janeiro, concludes, after many experiments upon animals, that coffee is directly useful owing to its assimilable principles, and is also especially useful indirectly owing to the large quantity of nitrogenised food which it causes to be consumed. It is probably superior to stimulants such as alcohol, because, taken in even large doses, it leaves a perfect equilibrium between assimilation and dis-assimilation, while at the same time permitting the tissues to be consumed to a greater extent. Although many points remain obscure in the mechanism of this impulse given to the most important organic functions, it is now known why the use of coffee is beneficial to those who wish to make a full use of their powers; it acts both as a stimulant and as a reparative agent, and, while permitting of a greater expenditure of force, and a greater consumption of nitrogenous substances, it clearly increases the capacity for work.—*Sanitary Record.*

QUININE ADULTERATION.—A most disquieting discovery was made last Friday in Paris. A dispenser at the Children's Hospital noticed that the powder on the bottom of an empty quinine-box presented a different appearance from that which he had taken out of the box. An examination showed that there was sulphate of quinine at the orifice and centre of the boxes, but that the rest was filled with sulphate of cinchonine and sulphate of cinchonidine. Investigations at other hospitals and in several druggists' shops gave the same result. The wholesale houses protest that they deliver the boxes just as they receive them, and that the sin lies at the door of the foreign manufacturers. However that may be, we hope that somebody either in America or France will be smartly punished for thus tampering with men's lives, for the typhoid fever so commonin Paris is in variably treated with quiniue.—*British India Journal.*

A DISINFECTANT.—Mr. Mattieu Williams notes that sulphate of copper may be usefully employed as a disiufectant. It may be bought at sixpence or less per pound (they call it blue vitriol) in the shops, and is really soluble in water. "I have lately used it," he says, "in the case of a trouble to which English householders are too commonly liable, and one that has in many cases done serious mischief. The stoppage of a soil-pipe caused the overflow of a closet, and a consequent saturation of floor-boards, that in time would probably have developed danger by nourishing and developing the germs of bacteria, bacilli, etc., which abound in the air, and are ready to increase and multiply wherever their unsavoury food abounds. By simply mopping the floor with a solution of these green crystals, and allowing it to soak well into the pores of the wood, they (the pores) cease to become a habitat for such microscopic abominations. The copper salt poisons the poisoners. It occures to me that this would be a useful and interesting subject of inquiry for young microscopists." The solution of sulphate should not be put into iron or zinc vessels, as it rapidly corrodes them, and deposits a non-adherent film of copper. "It will even," says Mr. Williams, "disintegrate common earthenware by penetratieg the glaze, and crystallising within the pores of the ware." Stone-ware resists them and they may be safely kept in wooden buckets.—*Knowledge.*

Correspondence.

To the Editor of the "Ceylon Observer."

MR. STORCK'S CURE A FAILURE IN FIJI APPARENTLY.

15th March 1883.

Dear Sir,—The bad opinion recently expressed in reference to the carbolic acid cure for leaf-disease is confirmed by the following extract I make from a letter lately received from an old correspondent of yours, who used to hail from Maturata, and who a short time ago, when visiting and reporting on a number of coffee estates in Fiji, also visited Mr. Storck's estate:—"I accepted an invitation from Mr. Storck to go and visit his place, and see his coffee and leaf-disease cure; so off again to the island of Viti Levu and up the Reva river about 50 miles; and there I saw Storck's coffee nursery and his cure for the disease H. V. He has small vessels made of tin or zinc, at the bottom of which is a little carbolic acid, and floating on the acid is water. His theory is, that the water absorbs a certain proportion of the acid, and through that medium is passed off continually in evaporization. He also said, in answer to my enquiry, that there was no danger of wind blowing the evaporized acid away, as *it* was heavier than the surrounding atmosphere, and could only be blown about among the trees, as it would always cling to the ground and not rise. This is a very pretty theory, but I doubt its efficacy, as I saw disease throughout all his nursery in all stages, and plenty of it. This he said was a fresh dose that he has had brought to his place, by coolies coming from a neighbouring estate up the river. Be this true or not, *the pest was there*, and whether it was a reappearance of the same disease, which had laid dormant, or been inoculated in the way he said, I can't say, nor can Mr. Stock." * * * *

He also says, further on, that he "found leaf-disease on some coffee which was on an island to windward of any other coffee estate, and to which, *no* plants had been carried, and the only way the place could have been infected must have been through the seed: which, if true, will upset Mr. Marshall Ward's theory, about the seed being a non-conductor, so to speak. I also observed a little bug but not much." This latter was on another estate, not on Mr. Storck's property.

From the above, I suppose we are as far as ever from finding out a cure for our deadly enemy H. V.—Yours faithfully.

A. C. T.

LOWCOUNTRY CEYLON TEA, UNASSORTED, SELLING AT 1s 8½D IN MINCING LANE.

Dear Sir,—The Culloden tea lately described as "pekoe" in the London sale list was the bulk from the whole tea on estate, and it fetched 1s 8½d. This is surely the highest average price got for Ceylon tea yet? I write this *pour encourager les autres*, especially lowcountry tea planters, this estate tea being only from 150 to 600 feet above sea-level.—Yours faithfully,

TEKSAB.

COFFEE LEAF FUNGUS: WHEN DID IT FIRST APPEAR IN CEYLON?

Dear Sir,—I see in your letter "From the Hills" in your paper of 15th, you say:—"I have no belief in the theory of some planters that *Hemileia vastatrix* existed in coffee before 1869." I now give you my experience of it. In 1863, a few days before Christmas, I walked from an estate near Gampola to one near Nawalapitiya. On the road there was a short cut through some coffee, which I took, and was surprized to find some yellow powder on my coat sleeves that had come off the coffee. Next was on Bellgodde estate in 1866: just after crop, the field above the store was looking shuck and I manured it with a mixture of pulp ashes and charcoal collected from the furnace of the steam engine during crop. As soon as the coffee was manured it got as bad a dose of leaf-disease as I have ever seen, but the coffee recovered in a very short time and I did not notice any more of it as long as I was on the estate, till August 1869, when I went to the Hope estate and there it was on the abandoned patches. The crop of 1869 70 contained a large number of black beans and that was what attracted notice to the disease.—Yours truly,

G. F. HALLILEY.

Mr. C. SHAND'S TEA DRIER.

Dear Sir,—I have read two letters on the subject of Mr. Shand's tea drier in your paper, and if the following remarks can throw any light on his system of drying tea I shall be glad if you would publish them. A machine somewhat similar to the one in question was invented about 6 years ago in Assam by a Mr. Barber. It consisted of two iron or metal boxes placed one above the other, about 8 inches apart, connected by a steam-pipe, and enclosed in a casing of wood; these boxes were fed with steam from a boiler outside. The greenleaf was spread out on the surface of the iron cases, and was thus dried in about 30 minutes. I saw this machine dry tea repeatedly, and also saw valuations from London on samples of the same. There was nothing said about a metallic taste whatever. In Mr. Barber's machine there was no escapement of steam, the heat was not *moist* but *dry*, and the valuations on the samples forwarded were equal to those of any other teas prepared over charcoal fires. The reason this drier was not a success was on accconnt of its not being able to fire off the green leaf quick enough to keep even a small rolling machine going. Since 1876 the "Sirocco" has been invented. There can be no comparison between the above machine and this, for the reason that no steam is required for the "Sirocco" and the green leaf is dried off in about one-half the time. I do not think any of Mr. Barber's machines were sold, as they could not compete with either Davidson's or Kinmond' hot air draft invention. I have not seen Mr. Shand' tea drier, but if it is simillar to Mr. Barber's, s believe as good tea can be prepared in it as over any charcoal fires, while it has the advantage of not burniog tne leaf, even with a careless fire.—Yours faithfully.

ASSAM.

NOTES FROM TEXAS, U. S. A.

Dear Sir,—I extract the following from an ex-Ceylon planter'sletter, who like so many more, has sought for "fields new":—"I arrived in New York after an ordinary winter passage. From New York, I left by emigrant train for this place. You would have laughed to have seen me huddled together with Poles, Italians, Germans and two English females. It took a week to get down here, and a week in a railway, sleeping and feeding when you can, is no joke. The climate is perfection. I am trying to get on a ranche in the capacity of what is here termed 'cowboy' or in reality 'stockman.' Several people assure me I need only wait a few days. There are any number of people to advise, but the best advice is I think that gained by experience. Sheep they say pay better than cattle; no doubt they are paying splendidly, the lowest rate being 15 per cent; but I have met a man who as a 'new chum' rushed in to invest and dropped all he had. *Experientia docet.* It is a roughish part, and cases of shooting are daily reported, but

nearly all take place in drinking shops and gambling resorts. The people are not a bad set, but all seem to chew and spit in every direction in the most disgusting manner. The food is bad; the meat being tough and cooked to a cinder, and everything supposed to be gebbled up in five minutes. Things are awfully expensive here. No one drinks anything but tea and coffee at meals. The stuff they call whisky is most nauseous. Although the place is supposed to be most healthy every second shop is a chemist's."
—Yours, R.

THE SALE OF CULLODEN TEA deserves a special word of notice such as our correspondent "Teksah" gives on page 841, for it seems the very good price of 1s 8½d per lb. was not for selected, but for the bulk of the estate's produce unassorted, and grown at only a few hundred feet above sea-level! Planters at as many thousand feet altitude must beat this price, before credit can be given for superior flavour; but the fact is that so far, the experience of tea planters at all levels in Ceylon is most encouraging to those interested in the future success of this industry.

ARTIFICIAL COFFEE.—SORNANI, of Pavia, in the *Ann. di Chim. appl., Farm. ed Md.*, announces that he has discovered quite a new and serious adulteration of coffee which is being practised by the manufacture of artificial berries. These berries are composed of the meal of beans and acorns, with chicory and some quartz powder to bring the mixture to the requisite specific gravity. A dough is made of these ingredients, which is cut by a special machine into the shape of coffee berries, and after drying has exactly their colour. Sornani says he has found as much as 50 per cent of these artificial berries mixed with the genuine. On roasting they take just the same colour as the genuine, but they are discovered by soaking in water, when the false berries soon fall to pieces.—*Chemist and Druggist.*

COFFEE BLIGHT IN BRAZIL.—The *Brésil*, a Rio journal just to hand, states that the minister of agriculture is at present engaged in devising measures for stopping the destructive progress of a coffee blight that has made its appearance on the plantations of that country. One of the councillors of state has forwarded a report to the minister on the present condition of one of the largest Brazilian coffee plantations, on which the annual yield of over two hundred tons of coffee has fallen to an insignificant amount. According to one theory, the blight is caused by a minute needle-shaped parasite, which is produced by millions in the roots; while others attribute the mischief to exhaustion of the soil and neglect of weeding.—*Planters' Gazette, March 2nd.*

WHEAT MILDEW.—Mr. E. C. Buck, C. S. Secretary to the Government of India, Revenue and Agricultural Department (Agriculture), wrote to the Secretary to the Government of Madras on 19th February as follows:—"I am directed to forward, for information and for distribution, through the Agricultural Department, to Revenue Officers, Agricultural Societies and others, twenty-five copies of a note 'on wheat mildew,' obtained from the Journal of the Royal Agricultural Society of England. I am at the same time to request that, with the permission of His Excellency the Governor in Council, inquiries may be instituted as to whether, as has sometimes been alleged, rust is more common in fields in which mustard is grown than elsewhere. The Government of India desires that the results of these inquiries, together with any additional information which may be obtained on the subject of rust in India, may be hereafter communicated to it." We shall give a summary of the note on wheat mildew in the *Tropical Agriculturist.*

SUGAR.—A writer in the New Orleans *Times-Democrat* estimates that 200 acres of cane, yielding 20 tons of cane per acre, will give 363,000 lb. of sugar worth 5 cents per lb. and 297,000 lb. of melasses worth 2½ cents per lb., the whole crop bringing $25.575. This is $127 per acre, which is two or three times as much as the crops in the West pay. He estimates, also, that with the improved processes in grinding, pressing and boiling, the crop of cane on 200 acres can be made to yield $45,890, or $229 per acre.—*Rio News.*

GREEN MANURING AND NITRATES are thus noticed in the Madras Model Farm Report:—Further experience shews, that in dealing with the very sandy soils of the Farm, "Green Manuring" is, perhaps, the most successful means of improvement. The practice, now adopted, is, in the hot season, when the weather is shewery, to sow with horse-gram a large area of the land without crop, the produce, either to be grazed by sheep folded on the land, or ploughed into the ground as green manure. There is, in most years, enough rain in June and July, to admit of this practice being carried out, though not enough for a regular crop to be matured, and secured, before the north-east rains set in. During the long preceding dry season, nitrification occurs in these soils to a very considerable extent, for though they are deficient in lime, they contain an abundance of soda, and this base is utilized in forming nitrates, and these being so very soluble would, if left in the land, be washed out, by the heavy rain of the monsoon; but when horse-gram is sown on the land, it greedily feeds on these nitrates, which, becoming worked up in organic combinations, are stored safely against removal by heavy rain. There must be an enormous waste of nitrates in this country when, after a very long dry season, heavy rains occur, as at the beginning of a monsoon. This shows the necessity for getting in the seed, as early as possible at seed time, before the setting in of the heavy monsoon rains, in order that the young plants may take up the nitrates and hold them safe. It has, in Europe, been repeatedly shown that during a year, as much as 40 lb. of nitrates per acre may be formed and stored in a good properly worked soil. Nitrates are so extremely valuable, the careful farmer should use every endeavour to utilize them thoroughly; and, the plan before suggested is, perhaps, the best that can be adopted.

GERMINATION OF COCONUTS.—Coconut cultivators in Ceylon will be interested in the following account of experiments on the Madras Farm:—Attention having been recently directed, in several scientific journals, to the possibility of hastening the germination of hard husked seeds, by steeping them in solutions of different salts and acids, especially in solutions of sulphuric acid, an experiment was made to test whether the germination of cocoanuts could thus be hastened. For the experiment ten fresh cocoanuts were taken, and they were treated as follows:—

Experiment.

No. 1.—Two nuts, steeped in water.
„ 2.— „ „ with 5 P.C. of sulphuric acid.
„ 3.— „ „ with 10 P.C. of „
„ 4.— „ „ with 15 P.C. of „
„ 5.— „ not steeped.

The nuts were kept in the water, and solutions, for five days. On the 1st of December last, the whole of the nuts were planted in a piece of suitable soil. The soil was watered when necessary. On the 12th of March one of the nuts sent up a vigorous shoot, but the others having failed to send up shoots, they were all dug up on the 31st of March, when they were found in the condition stated below:—

Experiment.

No. 1.—Both nuts had germinated well, and produced vigorous shoots.
„ 2.—One nut had germinated, the other was rotten.
„ 3.—Neither of the nuts had germinated, but both were in good order.
„ 4.—One of the nuts was just commencing to germinate, both were in good order.
„ 5.—One of the nuts was just commencing to germinate, both were in good order.

As far as can be judged from this single experiment, steeping in acid solutions seems to retard rather than to facilitate the germination of cocoanuts, while steeping in pure water hastens germination. The subject will, however, receive further attention, and other experiments will be instituted.

SUGAR.

There are at last strong signs of progress in some of the West Indies, and the old-fashioned methods of manufacture are doubtless doomed; for unless the colonists keep pace with the times the Cane Sugar industry cannot hold its own. The splendid island of Jamaica appears to be an exception to the progress elsewhere, although no place ought to produce better Sugar. It appears likely that refining kinds will fetch unusually low prices next Spring, and this will be a fresh incentive to improvements, which would save the waste, in weight or money, of practically two-thirds of the Sugar in the Cane. In Barbados the necessity for reform is now clearly recognised, and the transformation of the machinery on the island can only be a question of time. The *Barbados Herald* (an enterprising journal that has recently appeared in an enlarged and improved form, with a view to bring the local press up to the level of that of neighbouring colonies) has the following:—"Unusual activity prevails in the erection of steam machinery for Sugar-making. No less than eleven plants of steam machinery will be added to the steam Sugar works before the next crop, being, we believe the largest number ever erected in the course of a single year. We give a list of these new works:—

Estates.	Makers.	Erected by
Lower Estate...16 H.P.,	by Geo. Fletcher & Co.	—D.M.Simpson & Co.
Blackmans.....16 „	„ „ „	„ „
Bath .....12 „	„ „ „	J. J. Law.
Joes River.....12 „	„ „ „	„ „
Mount Wilton..25 „	„ „ „	„ „
Checker Hall...16 „	„ „ „	J. Rudder.
Hanson.....12 „	„ „ „	Gill Brothers.
Hopefield.....10 „	„ „ „	D. M. Simpson & Co.

This plant has a train of steam pans, thereby doing away with the old-fashioned copper wall.

Hampton.....30 H.P., by Geo. Fletcher & Co.(to arrive)—D. M. S. & Co.

Sandy Lane.....20 „ by A. & W. McOnie „

Goodland.....8 „ by Jas. Shears & Son „

In addition to these there is a vacuum pan at Halton, by Fletcher—B.St. Hill; boiler at Blowers—D. M. Simpson & Co.

These new works afford a pleasing evidence of activity and a desire to place the manufacture of Sugar in this Colony on a level with our neighbours who are ahead of us in the race of competition, the advocacy of which caused us to be gravely rebuked a couple of years back by a journal professing to speak with great authority on Barbados agriculture and its condition. There is still some Sugar from the last crop remaining unshipped, so that the returns are not finally closed. It is rather unusual to find Sugar remaining on hand so late in the season."—*Produce Markets' Review.*

TEA—PRUNING.

To begin with the teelah gardens, they are as we said mostly planted with China or a poor class of hybrid, and that bushes of this class make much more spurious wood, which it is necessary to remove in order to promote a vigorous growth for next season's crop, a more severe pruning can, with discretion, be applied to those old teelah gardens, than is necessary for young and flat gardens. For every one "bangy" or spurious shoot a hybrid bush makes, a China bush makes at least 10. The result of this spurious wood is a closing up of the centre of the bush, and a want of permeation of free air necessary to develop in the first instances strong flushes, and in the second being the foundation of good wood for next season's pruning. It is therefore necessary to be more careful to clean out all "bangy" or fragile shoots in a China bush than in a hybrid, and the China bush being more of a shrub than its brethern, the hybrid or indigenous, it is not necessary to allow it to grow so high, or we may say to prune to such a height, and we consider where bushes are uniform, a height of from 20 to 24 inches might be laid down. In addition to the above, it is necessary to be carefnl to remove all flowers, as the China bush has a great inclination to seed. With regard to the young gardens planted out since 1870, the class being higher, the pruning may be lighter, and the bush left to a height of say 2 feet 6 inches, cleaning out of course seed twigs, and having as much lateral growth as can be managed, so as to get as much surface to pluck off as possible. In the low flats planted out more recently, say within the last five years, the class of plant, when obtainable, has mostly been indigenous, and, as a rule, the lighter the pruning, the better has been the result. The Burma and Munipoore plant, as a rule, stand a more severe pruning than the indigenous, such as is found in the jungles of Assam and Cachar, and as the latter plant is only prevented from growing into a tree by successions of pluckings, and has all the characteristics of a tree, the pruning knife should be applied very tenderly. The latter class of plant mentioned is so full of sap, that if the knife is applied severely, it suffers immensely from bleeding, and in many instances from severe pruning, has been known to die back 3 to 4 inches below the pruning. The indigenous plant shows very little tendency to seed, unless the Burma and Munipoore, hence there is less necessity to prune hard; and we consider the only necessity to prune this class is, in order to keep it to a sufficient height to enable the women to reach up to pluck it.—*Indigo Planters' Gazette.*

TROPICAL PRODUCTS OF COLOMBIA.

A correspondent of the New Orleans *Times-Democrat* who visited Colombia along with a commercial expedition, writes as follows of the products of that country:—

The principal exports of Colombia are quina bark, coffee, balsam copaiba, rubber, cotton, sugar, dividi, fustic, cocoa, salsaparilla, hides, spices, indigo, hats, straw goods, cedar, mahogany, various kinds of furniture woods, gold, silver, amethysts, rubies, tobacco, bananas, and other tropical fruits.

Colombia, although its territory is traversed by the equatorial line, possesses a variety of climates. Its capital is situated nearly 9,000 feet above the sea, and enjoys a temperate climate. The vast plains that surround it are extremely fertile, and yield plentiful harvests of corn, barley, wheat, rye, and oats. But this fertile region is separated from the tropical localities and the coast by high and almost impassable mountains, over which the roads are narrow and rough, and transportation of freight is almost impossible.

The wife of one of the early viceroys of Peru, the celebrated Countess of Cinchona, was the first European to discover the merits of the incomparable medicine—quinine—the only drug that conquers the terrible malarial fevers that scourge the low lands of intertropical countries.

Throughout most portions of northern South America, where the land reaches an altitude of 3,000 feet, this precious tree is found in valleys and hillsides that flank the deep barrancas which separate the mountains from the lower country. So plentifully is its production that the first groves, which were discovered three centuries ago, are yet unexhausted, while new forests are constantly being discovered. Yet the method of gathering this valuable bark might lead a casual observer to imagine that the demand will soon far exceed the supply, for the careless Indians generally cut the tree down, strip the upper portion, and are too lazy to turn it over and gather the bark on the other side. The vast forests of Colombia can afford a supply of this bark for centuries yet.

Coffee does not thrive well in the extreme tropics, but needs a humid climate, a damp soil, and, in many cases, protection from the intense heat of the tropic sun. It is often planted between rows of bananas, or under the shade of frondose trees. It will not grow well in Colombia at a less elevation than 2,500 feet above the level of the sea.

The coffee of Colombia may be considered as equal to the Rio bean. It is highly esteemed in New York and Europe. A large quantity of the best kind is exported through Maracaibo, and is known as Venezuelan coffee. It is needles to say that New York enjoys almost a monopoly of this trade. Although it is a conceded fact New Orleans is the most advantageous coffee mart in the United States, her merchants, as yet, do not control a pound of this traffic.

Rice has become one of the staple articles of consumption with the poorer clases of the Colombians. Owing to the high price of American rice but little of it is met with in this market. Formerly England supplied Colombia with Rangoon rice, but some few years ago New York stole

the trade from her. Within the last two years the English merchants seem to have turned the tables upon their American competitors, and have recaptured the trade. How this occured it would be hard to say, as Rangoon rice may be shipped in bond from American ports.

There are many small rice plantations in Colombia, but such is the prejudice in favor of native rice that the latter brings even a higher price than either the South Carolina or Louisiana staple. Yet the native rice is much inferior to the Rangoon, on account of the poor method of cleaning in vogue, which is exceedingly primitive. The grain is flayed, the consequence of which is that the majority of the rice is either poorly hulled or is broken in many pieces, besides being mixed with dirt and sand.

The traffic in rubber with the United States is constantly increasing, while the Colombian product is estimated as equal to that of Para. The banks of the Sinu, the Atrato, the Magdalena and other interior rivers are fringed with vast forests of rubber trees, which afford an almost inexhaustible supply of the precious article.

The banks of the Sinu, the Atrato and Magdalena rivers are fringed with vast forests of cedar, mahogany, fustic, logwood, rosewood, ebony, and other kinds of furniture and dye woods. Cartagena does a flourishing business in this trade.

There were exported to the United States in 1879 over 1,000,000 cocoanuts, and this year but 40,000. Cause for great decrease: The destructive and all-devouring locust. The cocoa walks are augmenting, and this trade will, in a short time, resume its normal condition. If would not be well, however, for any of our fruiters to send vessels to Cartagena until the locust ceases its ravages. There is not a sufficient quantity brought to market to supply the home demand. The present prices here $40 to $50 per 1,000. Had not the locusts devoured the cocoa bud, it is safe to estimate the exports this year to the United States would have reached 2,000,000 of nuts.—*Rio News.*

ARTIFICIAL HATCHING.

SIR,—In reply to your correspondent "Heu," in your issue of the 10th instant, allow me to inform her that the constant heat required for hatching hens' eggs should range from 103° to 106° F. A *Hydro Incubator* or *Hen-wife*, such as I exhibited at the recent Agricultural Exhibition at Madras, is the best for the purpose. I had to work my apparatus out in the open under difficulties. Notwithstanding, I succeeded in hatching seven chickens on the first, and five on the second day with the help of a large empty packing case as a protection from the wind. The President, Secretary, and some Members of the committee and several ladies and others, besides a crowd of natives, inspected the incubator. One lady carried away two chickens, three died, and I had to give the rest away. The incubator excited much interest among the natives, who did not understand its operation, and said that I must be a "magician" to place an egg in a box and take out a live chicken. I was surprised to see that the *Mail* had not noticed the incubator. It was the fault of the Committee in not allotting a proper place in the building itself, where the poultry and pigeons were exhibited. Had this been done, the incubator would have attracted considerably more attention than it did, although I advised the Committee that I intended exhibiting an incubator in working order. I would suggest that your correspondent "Hen" get a *Hydro Incubator*, and the can then hatch all her eggs! It is a very simple apparatus, and can be worked by a cooly if the principle is properlyexplained to him.—JOHN SHORTT.—Yercaud, 12th March.—*Madras Mail.*

SACCHARATE OF COFFEE.—Carlo Paresi, in an Italiau journal, describes a new method of concentrating and administering the valuable and useful constituents of coffee as follows:—

R—Roasted coffee (best)	parts	1
Refined sugar	„	2
Warm water	q. s.	

The coffee is exhausted in a convenient displacement apparatus of all its soluble constituents, by means of the warm water; the clear brown percolate is mixed with the sugar, and evaporated at a temperature not exceeding 50° C. (122° F.), in a suitable apparatus, to dryness. Finally, it is reduced to powder, and kept in well-closed vessels. The evaporating vessel should be shallow, so as to present a large surface of liquid to the air; or, better still, a vacuum-apparatus may be used. The product is a brownish powder, of a coffee odor, a sweet and slightly bitter, very agreeable taste, and very soluble in cold water. Dissolved in boiling water, it yields a very fine cup of coffee. If made into a paste with tragacanth, it may be formed into tablets or troches—a very convenient form of use.—*Rio News.*

MANILLA HEMP PLANT (*Musa Textilis*) AND THE COMMON PLANTAIN.—Of these Mr. Robertson of Madras reports:—The plants have grown well under the same conditions as the ordinary plantain. They will not thrive, unless planted on a deep well-manured soil, under regular irrigation. Hence, the cost of growing plants, until they reach the stage fit for cutting is great; at Saidapet, this cost will amount to not less than 2 annas each. It costs about the same sum to bring into bearing a plant of the ordinary variety of plantain, but then, the bunch of fruit may be worth 4 or 5 annas at the least, whereas, the fruit of the *Musa textilis* is of uo value. There seems little or no probability of the *Musa textilis* becoming an established crop on this side of India. On the Western Coast, in some localities where irrigation and manuring are less urgently needed, the cost of producing the plants will be much less; and there, some experiments should be tried. Experiments might be tried in Ceylon, but the proportion of fibre to stem, from ·48 to ·81 per cent is discouragiusly low. The report proceed:—Some of the plants were in flower, and some bearing fruit, when they were cut. It was, of course, undesirable as regards the production of fibre, that the plants shoule, he allowed to stand so long as to produce frnit, but the intention had been to try to rear plants from the seeds, which was frustrated hy a cyclone prostrating the plants; they were therefore utilized as already shown. The men when engaged in separating the fibre were allowed to work in their own way, in the manner adopted in extracting the fibre of the common plantain. The process is extremely cinmsy, very slow, and very costly. With practice the men might have done better, but they never would be able, by their process, to produce prepared fibre at a cost sufficiently low to admit of it being sold at a profit. Some rough experiments were made in crushing longitudinal sections of the stems of the common plantain through an ordinary oat-crusher. In one experiment 20 lb. of plantain stalk yielded 7½ oz. of rough fibre, but even in this case the cost was about 2 annas per pound, much beyond the value of the fibre and the cleaning was very imperfectly done. For some purposes, it may be desirable to obtain roughly-prepared strong fibre, at a moderate cost, rather than a highly-prepared fibre, at a high cost. There is no probability of really clean fibre being turned out by the ordinary process, at a cost less than 6 annas per pound—a cost far in excess of the value of the fibre. The experiment with the corn-crusher therefore, suggests a direction in which economy may be secured in the extracting process. It was found that the iron rollers discolored the fibre. A stem-crusher formed of a pair of wooden rollers, has been constructed, but it needs further improvement. The experiments made with this machine will he noticed in the next report. Samples of this fibre, and of that prepared by the hand, in the usual way, have been sent to England for valuation. It would appear, than in this part of India, it would be better to give attention to the common plantain, in view to the production of fibre, or, a paper material, rather than to spend money in endeavouring to introduce *Musa textilis*. The fibre of the common plantain is utilized only to a very small extent; the plaut is grown everywhere, where water can be commanded and a suitable soil is available. The culture of the crop is well understood, and in the price got for the fruit all expenses are returned; thus, the stems are obtained almost free of cost. The following data, referring to an ordinary plantain, the stem of which was crushed for fibre, may be of interest:—

Date of experiment	17th Nov. 1880.
Weight of stem	52 lb.
Length of stem	7¾ ft.
Circumference of the stem near the ground	2 ft.
Yield of fibre	8 oz.
Percentage of the stem	1·04

It is evident, however, that the possession ofa suitable mill for crushing the plant is an absolute necessity, to admit of the fibre being produced at a sufficiently moderate price to compete in the market. Several mills for extracting fibres, are now advertised by different manufacturer in the United States, and in that couutry inquiries wills be instituted.

BEE-CULTURE.

TO THE EDITOR OF THE "ASIAN."

Sir,—I am endeavouring to introduce bee-culture into India, and have succeeded in introducing the Italian bee so far, that I have two stocks breeding.

I should be very glad of assistance from any one sympathizing with my object, and I should have great pleasure in doing all I can to assist any one wishing to try bee-culture on the most approved system.

I find difficulty in getting stocks of indigenous bees for trial. Dr. King found a stock of *Apis indica*, but before he could capture it for me the nest was robbed.

Will any reader of the *Asian*, favourably situated for finding nests of wild bees, kindly assist me to the possession of some stocks?

If a dead bee and a short description of the nest is sent I should be able to judge if the bee would be likely to repay the trouble of hiving, and I would give instructions for its capture and carriage.

I should also feel greatly obliged by specimens of bees from any part of India as I am working out the distribution of the honey bee.

The very small bee with a broad yellow band across abdomen (*Apis florea*) is not likely to repay the trouble of hiving, but I believe the larger bee, with yellow and black stripes over the whole abdomen, (*Apis indica*) would prove profitable, and I should like to get a few stocks of this kind as also of *Apis dorsata*, the value of which latter as a hive bee is problematical.

In hiving wild bees it is probably safest either to cut the queen's wings or guard the flight hole with orifices which will allow of the passage of a worker but not of a queen. Without one of these precautions wild stocks are likely to abscond.—John C. Douglas, Calcutta.

INDIAN BOXWOOD.

The possible supply of this important commodity from India was adverted to in the *Kew Report* for 1877, p. 27. Messrs. Joseph Gardner & Sons, the well-known timber merchants, wrote to Dr. Brandis, the Inspector-General of Forests in India, April 29, 1881, on the subject:—"We bought the parcel (about 5 tons), landed ex 'Strathmore' in London at the high price of £30 per ton. At these high prices the consumption will be very limited indeed. Can you kindly inform us what the prospects are of sécuring any large quantities of this wood—say 5,000 to 10,000 tons, at about £10 per ton—in Liverpool or London? We are drawing our present supplies from Russia and Persia principally; but there are so many fiscal restrictions, and the wood is also inferior to your Indian shipments, that we should prefer drawing all our supplies from India. At anything like £30 per ton only very small quantities can be used; at £10, however, it would probably be used very extensively for various purposes for which cheaper woods than boxwood are now used." To this communication Dr. Brandis replied, July 6:—"The boxwood resources of the country are very limited. . . . . There is no chance of such large supplies as from 5,000 to 10,000 tons being available from India." It is evident, therefore, that we cannot look to India to remedy the increasing dearth of boxwood. It would be obviously much to the advantage of any of our colonies that could send into the timber trade in quantity any wood which would be acceptable as a boxwood substitute. £10 a ton is calculated by the Indian forester to equal about 4s. the cubic foot. A further consideration is that the expense of conveying boxwood from the forests in India is very great, and unless a high price were reached its exportation would be impossible. The logs composing the parcel already referred to had to be carried partly on men's backs, and partly by carts, from the forests to Sahrunpur, and thence by rail to Bombay. A price of £30 a ton gave a profit of about 73 per cent; £17 10s. was consumed in expenses, and any price which did not cover this would of course involve loss.—*Kew Report for* 1881.

PLANT FOOD.

The nature and sources of Plant Food are naturally matters of great interest to all cultivators. From its universal diffusion, enormous quantity, and paramount importance this is particularly true of water. The rain it raineth every day, and that being so we are apt to be heedless of what the rain really does for us, to underestimate the amount of plant-food it supplies, the changes it exerts on the soil, and the loss of food that accrues when an excess of water causes a proportionate amount of food to be washed out of the soil. Any inquiry into these matters is likely to tend towards a more rational system of cultivation, and a better adjustment and utilisation of the resources at our command. These circumstances lead us to bring under the attention of our readers one of the most interesting and valuable of the large series of elaborate memoirs prepared at Rothamsted, viz., that on the amount and composition of the rain and of the drainage-water collected at Rothamsted. The report is drawn up by Sir John Lawes, Dr. Gilbert, and Mr. Warington, conjointly, and is contained in the last volumes of the *Journal of the Royal Agricultural Society*. The average annual rainfall for twenty-eight years is noted at 28·3 inches, and tables are given showing the actual amount in each month of each year from 1853 to 1880. These are local details, however, with which we need not further concern ourselves here. Adverting to the section on the composition of the rain-water, the quantities of ammonia and of nitric acid are the most important for our purposes, as these substances supply the plants with the nitrogen they require. It became, therefore, a matter of the first importance to determine the proportion of nitrogen existing in the form of ammonia in the rainfall. Without going into details, which would occupy too much space here, we may state as a general result that on an average of three years, with a mean rainfall of 28·4 inches, there are 6·1 lb. of nitrogen, as ammonia, supplied to the soil per acre each year; and that in addition, on an average of two years, 0·74 lb. of nitrogen are gained in the form of nitric acid, giving a total of 6·84 lb. of nitrogen per acre—a quantity considerably smaller than the mean quantity per acre of a number of stations in various other districts.—*Gardeners' Chronicle.*

TRENCHING SOILS.

The soil of which our gardens are composed may be roughly divided into three classes, viz., light, medium, and heavy, ranging from sandy soil on gravel to clay on a stiff impervious bottom. In the standard works on gardening and the formation of gardens excellent advice is given as to the nature and depth of soil to choose for a garden. In one we are told "it ought not to be too strong nor clayey, nor of too loose and gravelly a quality, but of a rich and rather a light pliant nature, capable of being wrought at all seasons without inconvenience, and of sufficient depth to allow the roots of all sorts of trees and plants to extend themselves with facility." If a garden can be laid out on such soil as this the owner may consider himself fortunate, but such is not to be found often, and we must deal with such material as we have and make the most of it.

Light gravelly soils are about the worst to deal with, especially in dry districts; and one practical example of dealing with a garden of this kind is worth half a hundred theoretical examples. The soil is very light, and on some parts of it gravel was found less than a foot below the surface; in other places there would be about 2 feet in depth over the gravel. We had to make a number of paths in the garden, and had a quantity of spare soil upon them; we therefore took out a trench down to the gravel where there was not sufficient depth of soil, dug out 6 inches of the gravel, and exchanged it with the soil from the paths, and as the trenching went on the gravel was removed from the bottom of each trench until the quarter or border was finished. There was a good deal of labour involved in this work, but it was a paying concern, as the soil from the paths had to be taken somewhere, and after it was removed the paths had to be made up with gravel. The whole garden was exhausted with the roots of so many fruit trees, and when young ones were planted they cankered immediately; it was therefore thought by many that fruit trees would not succeed. I was confident they would, and the result has shown that this confidence was not misplaced, as the garden is now furnished with healthy free-bearing trees.

Our first work was to prepare the ground for the fruit trees. It was trenched from 18 inches to 2 feet deep, according to the nature of the soil, and as it was poor

a layer of rotten manure was placed in the bottom of each trench after it had been stirred with a fork to the depth of 6 inches, another layer of manure was placed above this about 9 inches below the surface. The trees were planted at once, a few spadefuls of good loam from a distance being placed round the roots of each tree. Next season the ground was trenched over again to the same depth, and as the work proceeded the trees were moved with a whole mass of roots and replanted on the same ground; this time we worked about a barrowload of loam in amongst the roots of each tree, and when the trees were planted a mulching of good manure was placed round the roots of each.

I would warn the inexperienced against the danger of over-doing the work—that is, trenching all the good soil into the bottom, and leaving sterile stuff on the top, into which some crops will not push their roots. We find some soils with the clay very near the surface; the subsoil must in such cases be incorporated gradually, and rather than throw the second spit of such material to the surface I would fork the second trench over, and then place a layer of manure on it before throwing on the top spit from the next trench. The bottom spit that had been forked over and manured could be trenched up to the top next season. In many places it is quite necessary to dig up and incorporate the subsoil with manure before placing it on the surface, and even then only 2 or 3 inches should be worked to the top each season. It has happened in those cases where ground had been well trenched and manured; it would grow nothing until it was trenched over again, and the fertile mould restored to its orginal position. A failure of this kind would have been avoided by following the system I have indicated above.—J. Douglas.—*Gardeners' Chronicle.*

REPORT ON THE BOTANICAL GARDENS AT GANESH KHIND FOR 1881-82.

Mr. Woodrow, the Superintendent of the Botanical Gardens of Ganesh Khind, in the Bombay Presidency, gives us some very interesting and useful information in his report for the year 1881-82.

One of the most important items in the report is the fact that, from experiments made during the year it has been discovered that paper of a very superior quality can be manufactured from the bulrush, *Typha elephantina*. A native paper-maker in Poona made some good country paper from bulrush stems supplied to him from the gardens, and that without any great difficulty. Some pulp having been prepared in the gardens which having satisfied the paper-maker that the manufacture was practicable, the paper-maker reported that if he had to make more paper from similar material he could make it of much better quality than what he had already produced. In experiments conducted by Mr. Woodrow himself, it was shown that 4 oz. of the dried crushed stems, boiled with caustic potash, and beaten in a mortar, gave 2½ oz. of what was considered to be good "pulp." The weight per acre of dried stems obtained from two cuttings is four tons, and it could be produced in unlimited quantities at R15 per ton. Mr. Routledge, the English paper manufacturer, gives the value of "Tufa," the inferior sort of esparto grass, at £10 per ton delievered in England. If, says Mr. Woodrow, this bulrush material is worth half as much, it would be profitable to cultivate. Mr. Woodrow thinks that it would be probably profitable to cut it up, boil it with alkail and send it to the paper-makers in the condition shown as half stuff, because by this means much valuable plant food would be retained as manure.

Another interesting item in the report is the account of the experiments made in collecting caoutchouc from the *Cryptostegia grandiflora*. 83 plants of this climber were in existence in the gardens during the year, varying from three to five years old and growing in a variety of soils mostly fine alluvial. The method adopted for collecting the sap is described as follows:—100 paper bags were prepared, and after weighing each bag was fixed with thorn to the cut end of a branch, the wound being renewed ten times daily; and when the watery portion of the sap had evaporated, the bags were again weighed, and the increase taken as commercial Indiarubber. The average yield of the plants is stated to have been 20 grains, the average ground occupied by each plant being 1 square yard; if these plants, therefore, had been cultivated in a field after making an allowance for unavoidable blank spaces, Mr. Woodrow thinks the yield per acre would be 12 lb. The plants are said to suffer much from tapping, and would not bear the process more than twice in a year, which would give 24 lb. per acre of caoutchouc yearly. The cost of collecting was Re. 1 per lb., but this could be greatly reduced by improved methods of collecting. As the plants grow very slowly when young, the sap collecting cannot be begun before the third year.

Mr. Woodrow brings prominently to notice the large quantity of water-cress that has sprung up in the streams that run through the city of Poona, and which, he says, appear to be neglected by the people. Water-cress, it appears, has been proved by a French chemist to be rich in iron and iodine, and is believed to possess in a large degree the nutritive and antiscorbutic properties of the family it belongs to—the *Crucifera*. The fact that £150,000 worth of this herb is annually sold in Paris, that the value of the quantity sold annually in London is probably 30 lakhs of rupees, and that the average price in Manchester is twice the price of bread, deserves to awaken interest in the water-cress in Poona which would appear to be despised by the people.

The experiments made to show how exhausted sugar-cane land can be restored to fertility were satisfactory. The Superintendent says:—

"The ingredients which sugar-cane requires that are present in the soil in very small quantity are silica in combination with potash, soda, and lime in the soluble form called soluble silicates. To reproduce these soluble silicates is not difficult, but in this country, it will be expensive and it is not practicable in a short time.

"The process necessary is to manure with 2 tons per acre quicklime, and 10 loads per acre wood-ashes, sow and plough in a green crop such as "Tag" *(Crotolaria juncta)* or "mohria" *(Sinapis nigra.)*

"During four years manure as usual I cultivate such crops as the soil and markets suit, giving the preference, if practicable, to the pulses, and avoiding the cereals, in any case only one corn crop can be permitted. After this treat in the usual manner for sugar-cane and an average crop may be expected."—*Asian*

TREATMENT OF SEEDS.

Have any of your readers ever remarked the difference that treatment, as regards moisture and watering, makes to newly-sown seeds when they vegetate? I believe that, in nine cases in ten, the first thing the gardener does after sowing a pot of seeds is to water them thoroughly. Some even steep certain seeds in water previous to sowing—which may be advantageous in certain cases; but I am far from thinking that immediate soaking of newly-sown seeds is beneficial. I first noticed this in the case of melon and cucumber seeds, viz., that those seeds which were not watered for some days after sowing germinated most freely and more healthily. Those which were well watered when sown were weakest and palest in the foliage, and the difference was quite apparent to any one. Since then, I have carefully abstained from watering all seeds we are particular about, until they have begun to swell and burst their scales. Several physiological explanations of this suggest themselves; but here I only state the fact that seeds are better not watered till some little while after being sown. I am speaking of seeds sown under glass in the above cases; but I have noticed the same thing in the case of outdoor seeds, particularly peas, carrots, &c. Peas sown in friable, dry soil, and which experience a short spell of dry, sunny weather afterwards, come up strongly, and fewer seeds rot in the ground as old seeds are apt to do, especially of the later and more tender marrow kinds.

This may not appear a great matter; but we know that in the case of fine seeds, sown under glass, there are often great disappointments, and much depends on management. The seedsmen, or the quality of the seeds, is not so often to blame as people sometimes think. No gardener of experience expects more than a liberal percentage of his seeds to grow, while some are always doubtful; but unless the sowing is managed skilfully, many things may fail partially, or altogether. Covering seeds too deeply is one of the most fertile causes of failure, for many a failure is due to this, and the cause never suspected. Big seeds of vigorous growing plants—like broad beans, for

example—have almost as much power as potatoes to push up through a heavy covering of soil; but, with exceptions of this kind, no seeds should be covered deeply, and small seeds should hardly be covered at all. It is necessary to surround them with sufficient compost to keep them always moist, but more than that is not needed. The seed should, in the first instance, be sown on a perfectly level and even surface, and then sprinkled over with a compost put through the finest of sieves. I am speaking of seeds like the primula, cineraria, lobelia, carnation, calceolaria, and the like. It does not matter so much what kind of compost the seeds have got under them, but that above them should always be fine and open, consisting in large part of sand and peat, or leaf mould, which will be found suitable for covering any seeds. But, rather than put too great a depth of even this light compost over very small seeds, it is better to barely cover them out of sight, and place a sheet of newspaper over the pan, or box, till vegetation takes place. The only object of covering seeds seems to be to keep them moist, and this can be effected with a paper cover only, laid over the box. Begonia seed is often sown in this way, it being too fine to be covered.

Next to these matters comes watering. A pot or pan of fine seeds is soon cleared by a careless waterer or an awkward watering-pot. The rose of the watering-pot should be very fine, but have many holes, and small as they can be bored, so that it will just deliver the water in a gentle spray or mist, and not with sufficient force to dislodge the seeds or disturb the surface of the soil. Seed-pans should never be floated with water, or the likelihood is the seeds will all swim to one corner, and that many of them will be buried, and never come up.

The rules to be observed in the case of outdoor seeds, flower seeds, and vegetables are the same. Sow when the soil is in an open, friable state, and cover thinly, in proportion to the variety of seed. Peas will push through three or four inches of soil, but more will vegetate under less top-weight, especially in heavy soils. The nature of the soil should always be reckoned with. Seeds sown in light sandy soil are safe under a depth that would kill them in a stiff soil. Hence the rules laid down in calendars are often misleading in such matters. In one garden I know of, the old gardener, who sows many annuals in the flower garden where the soil is heavy, covers all the seeds with a dry compost composed of river-sand and leaf soil. If he were to use the ordinary soil, and rake the seeds in in the common way, he would probably not have the success he has.—S. W.—*Field.*

PLANTING IN NATAL DURING 1882.

To particularise more fully what our planters have done, we may say that the year will be long remembered by that community in consequence of the absence during the summer and autumn months (January, February and March) of the usual rains. Growth was seriously checked, much injury being done to the crops. We find, notwithstanding a considerable advance in the area under the cultivation of the sugar-cane, a much-diminished out-turn of sugar for the season. Canes have, although light in the ground, in some measure made up for a part of the deficiency by the richness of the juice obtained. The quality of the sugar has shown an advance on last season's work. The adoption of standard samples by the Chamber of Commerce will tend to encourage manufacturers to aim at making their sugar up to sample. The effect of the disturbance created by the Zulu war is still felt by our planters, in the absence of the average acreage of ratoons. A larger breadth of land than usual has been cleared and planted with cane. Planters have turned their serious attention to cultivating improved varieties of cane —principally importations from Mauritius. Green Natal, on good land, may even on indifferent land, with good cultivation and manure, still bears the palm as the cane most fitted for the climate. We are glad to learn that manure is used on most estates. Artificial manures are in request; valuable compost heaps are found at most of the mills. The young canes are very backward in consequence of the want of moisture during October and November. Unless more favourable weather intervenes, the crop for next season will be unusually light. The disease called "smut" caused considerable anxiety during the early part of the year. A commission was appointed by the Victoria Planters' Association to enquire into and report on the disease. A very able paper was the result of its labours. The attention thus drawn to the subject led planters to take steps to eradicate the disease. Marked success has attended their efforts; the ravages of the disease not only having been checked, but in a fair way to be stamped out. Much anxiety was caused during October and November by a spell of hot, dry weather, but all anxiety was dispelled by the abundant rains, accompanied by the fine growing weather of December. The acreage of mealies reaped during the year was larger than in any previous year, principally owned by Indians. The crop was a light one; had it been otherwise, the price would hardly have been remunerative. It was not until November that the price of mealies rose over 12s. Tobacco is now principally grown by Indians, its cultivation is rapidly extending. There seems no difficulty in disposing of any quantity of this crop in its unmanufactured state. It seems strange that the European grower, with his greater knowledge and greater skill, cannot compete successfully against the Indian in this crop. The curing of the Indian tobacco is of the most primitive kind. Tea has, through the energy and public spirit of Mr. Hulett, come into prominence. It promises to soon become a paying industry, the only seeming difficulty being of preparation for market. Coffee, as it always does, promised fairly well and disappointed its backers. It has again blossomed magnificently; it is impossible to say what the result may be, most probably another failure. There is very little coffee left under cultivation, and the outturn is unappreciable. Several good samples of cotton have been grown from selected Upland American cotton, and imported direct from New Orleans. The crop grown by Mr. Osborn, of Umtata, from this seed is a fair sample of Upland cotton, the colour is good, the staple quite up to the average, its only defect being that it is rather too much mixed with leaf. All the other samples of cotton produced were from the same seed, but several had been altogether spoilt in the ginning,—thus it came to be thought by the uninitiated that they were other varieties. An effort was made to induce the free Indians to cultivate the plant, but hitherto with but indifferent success. Public attention has been directed during the year to the production of fibres. Mr. de Chazal presented a paper on the subject to the Planters' Association, calling attention to the work done in Mauritius, and giving much valuable information and instructions as to growth and manufacture. Mr. Blamey of Milkwood Kraal, laid before the same Association some very interesting specimens of rope made from the Fourcroya, and also made some interesting remarks thereon. A commencement has been made in this industry; there is every probability that it will develop large proportions. The several associations have been active during the year, much good resulting from the interchange of thoughts and ideas on the different subjects discussed. The question of pollution of streams remains *in statu quo* so far as the Government is concerned, the Bill having been withdrawn last session of the Council. We understand that during the next few months Mr. Dumat will make arrangements for turning the refuse from the Mt. Edgcumbe Central Mill into a portable manure, thus doing away most effectually with any chance of pollution of streams. The sub-contractors for the Ladysmith extension have mainly relied upon the coast districts for their supply of labour, thus the labour market has been much straitened. A constant stream of toilers of both colours passed through the country; large numbers of natives were tempted to leave employment on the sugar estates for the railway. The supply of indentured Indians has not nearly met the demand; the immigration from India is languishing; but, as we have already shown, the Trust Board has done all that lies in its power to revive it by the appointment of so able a commissioner to proceed to India as Colonel Mitchell. To add to the general scarcity, during December the majority of Zulus left their works suddenly to return to their kraals, to watch the course of events following Cetywayo's return. Native labour in the past has been at all times unreliable, and promises in the future to be still more so. The coast railways have worked satisfactorily during the year; very few complaints are heard. The system seems in good working order. The rates of carriage remain too high for the due development of the country. It is considered that a reduction even at the cost of a land-tax would be for the benefit of the country. The extension of the lines north and south without delay would open some magnificent

lands, which a taxation might throw into the market on reasonable terms. Holders of unoccupied lands are reaping annually the benefit of the industry and experience of occupiers without contributing their fair share to the cost of the government of the country. Their selfish policy is preventing the settlement of some of the most suitable land in the colony. The commercial depression has not materially affected the agriculturist. The financial corporations of Natal do not afford to agricultural enterprise those fostering facilities which do so much for the advancement of other countries.—*Natal Mercury.*

EXPERIMENTS IN COCOA CURING.

[The following letter, addressed to a cocoa planter, has been placed at our service for publication.—Ed. *T. A.*]

Colombo, April 2, 1883.

Dear Sir,—I have to apologize for having delayed so long my promised report on the experiments I made with cocoa pods you were so kind as to place at my disposed; one thing or another came in the way of my putting the results on paper. Your letter of the 31st ultimo hastens by a few days the letter I intended to write to you. One of the chief objects I had in view, in asking you to lend me some cocoa pods, was to ascertain whether I could hasten the process of fermentation, by the application of a regular and constant higher warmth than that of the atmosphere. I am sorry to say that all my experiments in this direction were complete failures; the result therefore is that instead of preserving the pink color of properly fermented beans, all I experimented with are very dark and coated, so far as the outward appearance is concerned. I attribute this complete failure, in a great measure, to my previous unacquaintance with the ordinary process, and also with the nature of the mucilage to be dealt with.

I found that if the whole of the mucilage was not got rid of, what was left, immediately turned black by exposure to the atmosphere, and very quickly got mouldy—all this of course you know, and I only mention it as an explanation of my failure in the object I had in view. But if the result of my experiments was unsatisfactory in one respect, it was satisfactory in another; it proved to me what you no doubt know but which I did not, that fermentation of the beans is only practised for the purpose of removing the mucilage; that process being perfectly unnecessary for imparting the true chocolate color to the cocoa kernels; this being developed in course of drying the beans by the conversion of the watery juices of the kernel into the coloring oil which, forms so large a portion of the cocoa bean. The satisfactory point ascertained by the experiments is, that not only may the whole of the mucilage be god rid of without any fermentation whatever, by a very simple and easy process; but the mucilage itself can easily be converted into a valuable product instead of being wasted as by the present method.

I found by experiments that considerably more than half of the mucilage may be separated from the beans, by washing them or rather mixing them with a little water, and by agitating them in a revolving cylinder with perforated holes for the fresh sacharine liquor to run into a trough, which would convey it to a clarifyer which is the first process towards its manufacture into sugar.

That portion of the mucilage next to the beans, especially that adhering to them, is more refractory and difficult to separate, but I found that even this could be easily rubbed off instead of got rid of by friction. I should think a machine—similar to a washing machine, would answer the purpose on a large scale. I may mention that in my small experiments a quantity of small stones was mixed with the beans to chafe them when revolving, sufficiently to remove the whole of the mucilage, and preserve it before fermentation set in.

If cocoa planters are indifferent to the utilisation of the enormous quantity of saccharine, contained in the mucilage; or think the result will not compensate for the trouble. I still think a much better and speedier way of getting rid of the mucilage may be hit upon, than by the slow and wasteful process of fermentation. As a half or three-fourths of the mucilage can be removed at once by simple agitation, there is only the last coating to be dealt with—this could be rubbed off by some process or other. I obtained a beautiful sample of cocoa by rubbing the mucilage off with a rough towel. However, I have no intention of suggesting any particular way of removing it. I only wish to say that I think for the reasons given above, that fermentation is a wasteful and an unnecessarily slow process. At present my interest in this portion of the question is very insignificant.

I will now advert to the point in the curing of cocoa in which I am particularly interested, and that is whether the principle of my tea-dryer cannot be applied to the drying of large quantities of cocoa (which, like the produce of its palm namesake, contains so large a quantity of oil as to render it very susceptible of mildew, in a damp atmosphere) until the whole of the moisture is evaporated or dried out. I believe that my tea-dryer can be advantageously used for the purpose of drying cocoa in a manner which would not injure or remove the outer skin or parchment. The result of my experiments is to satisfy me, that in the first instance, the drying should be very gradual though continuous, to allow of the watery juice to evaporate gradually, and for the coloring oil to take its place. If dried too quickly, the parchment will split on the germinating side; the watery juice will evaporate, and the kernel become dry before the oil has permeated the whole of the kernel; the result will be, that some of them will dry white or mottled, and the parchment will crack in a way that will render it liable to become detached from the nibs in transport, or manipulation.

My advice then is, if my dryer is used, to spread the cocoa fresh from the process of removing the mucilage on the hot surface rather thickly, say four or five inches thick, and keep it there until the whole becomes warm throughout. I would then remove it into bags, and let it stand for a few hours until a fresh charge is ready to be put into bags, I would then replace the first charge until it again became warm throughout; by thus alternating the charges, a large quantity of cocoa could be dried gradually, which I believe to be a necessity in cocoa curing. I assume that drying cocoa by artificial means would only be resorted to when it is impossible to dry it in the ordinary way, viz., by the heat of the sun, this method being obviously the cheapest one, though by no means the speediest, and during the greater part of the year the climate of the mountain zone of Ceylon renders it almost impossible to sun-dry cocoa satisfactorily on the estates. For the purpose of drying large quantities, a considerable area would be required. You can ascertain the cost by taking two-and-a-quarter rupees per superficial foot as the basis of calculation. The heat generated by the drying machines would, in a closed store, with ventilators, hasten the drying of half dried cocoa and prevent mildew and discoloration.

In communicating the results of my crude experiments, I desire only to turn your thoughts into the channels I have indicated. I have not the materials for continuing the experiments, nor can I afford either to buy them or the appliances for doing so. You will however be able to continue them on the hints I have ventured to offer.—Yours truly, C. SHAND.

P. S.—As the oil in cocoa beans liquifies at 120 degrees, the process coloration is hastened by drying gradually on a surface heated to 170 degrees.

Imports of Caoutchouc in 1882.—From Messrs. Hecht, Levis and Kahn's Caoutchouc Report for 1882 we learn that "in spite of the high prices ruling throughout the year, the consumption of all kinds of indiarubber has steadily increased and the stocks remaining at the expiration of a year of large imports are very moderate." Fine Para rubber, it seems, gradually declined in price from 3*s.* 9*d.* to 3*s.* 5½*d.* in February; then, owing to an enormous American demand, rapidly rose to 4*s.* 10*d.* in May, falling again in August to 4*s.* 1½*d.* It subsequently advanced to 4*s.* 11*d.* in October, and in December last it stood at 4*s.* 7*d.* The production of Para rubber is stated to be steadily on the increase. The imports into London and Liverpool amounted to 3,948 tons, against 3,855 tons in 1881, showing an increase of 93 tons. Of the total exports from Para the United States have taken about 6,000 tons direct from Para, being again an increase of 800 tons as compared with 1881. The total exports from Para to all ports are estimated at 10,200 tons against 8850 tons in 1881, being an increase of 1,350 tons against 1881.—*Gardeners' Chronicle.*

PLANTING ON THE HILLS OF CEYLON.

Lindula, March 23rd.

Weeds on Plantations.

As the theories of Mr. Halliley and those who agree with him in favour of weeds are merely matter of opinion, we who are sceptics can safely smile at what we do not admit. We are placed in a different position when Mr. Halliley asserts that he had personal experience of the existence of *Hemileia vastatrix* on cultivated coffee, first in December 1863, or 5½ years previously to the date (May 1869) usually assigned to its first appearance in Ceylon ; and again in 1866. I do not for a moment suppose that Mr. Halliley would assert that of the truth of which he was not perfectly satisfied ; but he like other human beings is liable to error in the observations he makes and the conclusions he draws. If, in December 1863, *Hemileia vastatrix* existed on coffee between Gampola and Nawalapitiya, and that in so a virulent a form as to cover Mr. Halliley's coat and sleeves with the yellow dust of its spores, then several questions arise :—The late Dr. Thwaites, C.M.G., was then living in the island, and not only on the *qui-vive* to convey to Messrs. Berkeley and Broome specimens of all the Ceylon fungi, but as much alive then as he was in 1869 to the duty of informing the Government and warning the planters of Ceylon of the appearance of a new enemy of the great industry of the Colony. The *Observer* was also as ready to publish information on such an important matter as it is now. But we have never heard that Mr. Halliley or anyone else communicated on the subject either with the Director of the Botanic Gardens or with the press. If the disease existed as described in 1863 and in 1866, and of course in the intervening years, how can we account for its comparatively latent character seeing the rapidity and virulence with which it spread over the whole coffee cultivation of Ceylon, when first noticed by science and recognized by the great body of planters in 1869, appearing almost simultaneously (where equally with Ceylon it had never been authentically noticed before) in Southern India, Sumatra, Java, the Straits and practically the whole eastern world? Mr. George Wall was in 1863 and in 1866 as much interested in coffee as he was in 1869, and at least as keenly observant as he is now ; but we are not aware that, although, like everybody else, he noticed yellow leaves on shuck trees, he ever saw or made sign of having seen before 1869 the fatal dust which covered Mr. Halliley's coat and sleeves as he asserts in 1863. As Mr. Halliley is a six-footer, does it not seem curious that it was on his coat and sleeves he specially observed the yellow powder? May he not have passed under trees other than coffee, affected by a fungus other than that which is peculiar to coffee? And seeing that Mr. Halliley attributes the present unfortunate condition of our coffee mainly to want of large applications of fertilizing matter, how does he account for his treatment of "shuck" coffee with pulp, ashes and charcoal causing it to develop as bad a dose of leaf-disease as ever he had seen, from which, however, the coffee recovered in a very short time, the disease, apparently, not spreading even to immediately adjoining coffee? There may have been *a* bad leaf-disease in 1863 and again, in 1866, but, with all deference to Mr. Halliley, we are not satisfied that it was *the* leaf-disease which, since its sudden and rapid development in 1869, has proved so fatal to the interests of coffee planters in Ceylon and India, and which is telling with disastrous effect, also, in many portions of Java and the Eastern Archipelago generally: which indeed threatens the whole coffee cultivation of the globe.

Compensation of Dew for Absence of Rain.

What is the theory as to the extent to which dew compensates for the absence of rain? and what about the proportion of ammonia in each? My inclination is rather to believe that dew is freer from chemical constituents than rain, clearer, colder and less beneficial to vegetation? Whether "blobs" of dew do not sometimes help to blister leaves by concentrating the sun's rays, burning glass fashion, is also a question on which I should like to have the opinions of experts.

The Dying-off of Cinchonas.

I had been asked to go and see and have a talk about cinchonas, and just before sitting down to record a few of the impressions left by this visit I received from Maturata a letter which I place here, only premising that I evidently failed to make my correspondent understand that the dying-off and uprootal of cinchonas of which I wrote was on the ground of a neighbour, who, I had hoped, would escape experience which had *previously* been ours on Abbotsford. At present our cinchonas are singularly healthy, cases of the *blistering* canker being few and far between and root-canker equally rare. The new and anomalous gum leaf disease seems, with the occurrence of genial weather, to have abandoned eucalypts and cinchonas, and is now only apparent in the shape of white round spots and patches of discolouration on some of the older tea leaves "Things like this we know must be" in all cultural operations, and while we cease to be dismayed at their occurrence let us welcome all information in the direction of remedial measures.

Shaving off Cankered Cinchona Bark.

Our friend writes :—

"Maturata, 26th March 1883.

"By the *Observer* of 22nd inst. I am sorry to learn you are, like myself, suffering very severely from canker among your cinchonas* and are about to root them out. As the following experiments may be of service to you, I have much pleasure in placing them at your disposal. Should you deem them worthy of attention I shall be glad to hear what success they have with you.

"A year ago the idea struck me from seeing a succirubra tree on the roadside with the top broken off, where it was cankered, sending out fresh shoots, one of which had attained some six inches in height. This set me to work on a few young succirubra trees suffering from stem canker, off which I shaved the diseased as also a portion of the healthy bark, all round the part affected. When I left, two months after, the trees were looking healthy, but had done little towards renewing their bark ; since then I have had no opportunity of seeing or hearing about them.

"In Sept. last, finding root canker spreading here, I set to work on three trees ; unfortunately, by mistake, at different times, these trees have been cut down by my coolies : the last was brought in three weeks ago. My treatment of it and its appearance up to the time it was coppiced, was as follows :—I began by shaving out all the diseased bark aboveground ; the tree stood from 10 to 12 feet high; the branches, with the exception of a few near the top were dead or dying, and the leaves sick or unhealthy. The bark at the ground was diseased three parts round the tree and ran upwards in strips, the longest extending to a height of 3½ feet ; this I shaved off and a portion of the healthy bark adjoining it ; finding the disease had, in some places, eaten right into the tree I shaved until I came to healthy wood, taking, in one place, quite a sixteenth of an inch out. Having shaved the remaining healthy bark, with the exception of a narrow strip which I left, the dying branches were cut off and the tree left. In the course of a few weeks most of the leaves fell Gradually new leaves began to appear, the shaved barks to renew, and when the tree was coppiced there was a fair flush of new leaf, also one or two shoots springing from the stool, which, during the past three weeks, have made great strides, and are now strong and healthy. Although my experiments have in neither case had, from personal

* No : see explanation prefixed.

observation, time to come to maturity, still the way in which the latter came on, while other trees around were affected and died, augurs, I think, well for such treatment being successful, and I now mean to apply it on a large scale, having, I am sorry to say, a terrible dose of this disease in my succirubra fields.

"I think in shaving and not covering the healthy portion of the bark as I did I was wrong."

We had heard of, and on a small scale practised by way of experiment, this process of shaving off cankered bark, but we certainly had not cut into the wood or covered the shaved portion. Our correspondent's treatment is what the doctors would call "heroic." Indeed a similar process is common enough in human surgery, a cankered limb being often removed so as to save life in the remaining portion of the body. The new blister-canker or mortification generally first appears on a small portion of the stem, and were it attacked and removed in its incipient stage and the wound covered up, it seems highly probable that tens of thousands of valuable trees might be saved.

BARING THE ROOTS OF CANKERED CINCHONAS.

Our correspondent refers to root canker as being curable by his shaving out process, and one of the first matters which engaged our attention on visiting St. Regulus was the process adopted to counteract this deadly affection. Mr. Ewen Hay Cameron claims that on St. Regulus was first tried the root-baring process, and that, should its success be fully and finally established, the credit of initiating the treatment should be awarded to Mr. Parsons, the same gentleman who adopted the simple yet effective measure of bringing grubs to the surface by spreading sacks over the ground. Mr. Parsons, like Mr. Cameron himself, is an enthusiast in all that relates to cinchonas. It seems that more than a year ago Mr. Nock of the Hakgala Gardens was requested to come down to see and if possible suggest a remedy for trees suffering from or threatened with root canker. Mr. Nock was of opinion that the canker, if not caused, was aggravated by the damp earth which was generally heaped against the collar of the plant. This was new doctrine, certainly, for a few years back one of the great remedial measures enjoined was to heap earth above the plants in the shape of horizontal pyramids so that the rain wash might be diverted from the roots and go down on each side. To bare the roots would surely give a severe shock to the trees, and I reminded Mr. Cameron of the treatment to which vines in Ceylon are subjected to compel them to bear fruit. "If," I said, "your object was to obtain a copious supply of seed from your trees then I could understand the root-baring process and the inevitable shock which accompanies it." Mr. Cameron in reply stated that the process fell greatly short of that applied to the vine, inasmuch as only the large spreading roots ought in the case of the cinchonas to be bared, it being a defect in the process if the feeding rootlets were exposed or cut. It seems that Mr. Parsons followed out Mr. Nock's hint by reflecting that in passing through a forest it would be observed that a great proportion of the trees had their large lateral roots standing aboveground. What the forest trees found good for them might be good also for the cinchonas. "All right,' we remarked, "for groves of cinchonas which, like forests, have a self-supplied shade; but here I see the process applied to isolated trees and to the rows of trees on each side of your paths. The roots being exposed to the full blaze of the sunlight and heat, the trees must surely suffer." "It is only natural to apprehend such consequences," was the response, "but the trees you are looking at have had their roots exposed for more than a year, and I ask you if you ever saw finer or healthier growth than they present." A large number of the plants referred to were officinalis, the kind most liable to disease and premature death, and we could only say that never in Ceylon had we seen finer trees: those on Dodabetta were no doubt larger but then they were much older. Mr. Cameron's oldest trees (officinalis) are only seven years planted, and yet a large proportion of them range about 19 inches circumference of stem; while a fine specimen of robusta is 21 inches.

IS *Cinchona robusta* A HYBRID?

By the way, Mr Cameron, while believing in hybrids, does not regard *Cinchona robusta*, the tree of the vigorous growth and specially *dark* green, glabrous leaves, as a hybrid, but as a distinct form. Has any planter been able to set this question at rest, by following hybrid plants from their infancy until fairly developed? Our impression was and is that experience had quite settled the fact that from a union of succirubra and officinalis resulted hybrids some of which leaned to the succirubra parent in foliage and were often pubescent, while others looked more like officinalis, having dark green, glabrous leaves, but far excelling officinalis in tall and luxuriant growth. Mr. Cameron's officinalis, however, left little to be desired in vigorous growth or height, whether the seven years old specimens along the paths, or those in a couple of splendid groves in which there is scarcely a vacancy.

SUPERIORITY OF CUTTINGS OVER SEEDLINGS.

Mr. Cameron is inclined to attribute the success of these trees to the fact that they have originated from surface-feeding cuttings obtained from Hakgala. This profession of faith in the superiority of cuttings over seedlings is another proof of the wide differences of opinion which exist or have existed amongst those interested in cinchona culture. I well remember that when the "dying-out" process first commenced on a large scale, after rainfall so excessive as to lead to a landslip in the Hakgala gardens, the feeling was strongly expressed, amongst others by a well-known Uva visiting agent, that the premature decay of the plants was due to the very fact that they were derived from cuttings and so had no taproots. There can little doubt, on the other hand, that much fatality has been due to the collection of seed from immature plants, and it is a characteristic of *C. officinalis* to flower and seed at an early age,—at least in India and Ceylon. Plenty of seed can now be obtained from well-matured trees. Mr. Cameron believes in and practises the excision of blossom and fruit stalks from his younger trees; but apart from some millions of selfsown seedlings, there is seed enough on the seven-year-old officinalis trees to stock the whole country-side. For the young plants in his two officinalis groves Mr. Cameron obtained a good market last year, but it was a great disappointment to him that, after having had, for a fair period, a practical monopoly of ledgeriana seed from Java, he was able to sell so few plants from his nurseries,—only enough to cover his expenditure, instead of giving him, as he had hoped, a couple thousands of pounds profit. In better times, it cannot be doubted, the whole of the plants in the ledgeriana nursery would have been readily bought up at the price of R30 per 1,000 fixed on them; but what is to be done when not only are there planters with no money to spend: but agents who have no funds to advance: estate agents here being often themselves but the agents of wealthy firms or moneyed men at home, whose faith in Ceylon has failed from the unfortunate decline in coffee?

HARD CASES.

Some of the tales afloat of descent from affluence or competency to poverty and worse—a burden of debt—are heartrending. Comparatively happy are some who get released from liability by giving up their property. Take one case: two gentlemen paid a few years ago £18,000 *cash* for a coffee estate which had just yielded 6,000 bushels of parchment, worth, then,

over R10 per bushel. It began to decline, until last year it gave only 600 bushels, and "the agents" took it over. If only the analogy of past crises is followed, this property may yet revive to more than its pristine value, especially as it is well supplied with cinchonas. That may be sufficient apology for my digression.

Mr. Cameron's succirubras, six years old, are splendid trees, and a large portion of St. Regulus is filled with cinchonas of all ages, including, as the most recent addition, a number of ledgerianas of the best type. My own belief in the almost unique success of cinchonas here—for there is only one small patch where failure has been met with—is that not cuttings or seedlings account for it, but the almost perfect conditions of elevation, climate, but especially *soil*, which are combined on St. Regulus. The elevation is about 4,500 feet above sea-level, and we could see no trace of damage from tearing winds.

CONDITIONS FOR SUCCESSFUL CINCHONA CULTIVATION.

But the great point in favour of successful cinchona culture on this estate is the existence over the greater portion of it of a gravelly but free soil, such as has been found specially to suit the fever plants in Ceylon; just as the free deep mould of southern India and the decomposed lavas of Java, respectively, have also suited the Andean plants. Not that there is not some excellent coffee on St. Regulus, from which a fair return may be expected. But nature intended the place for what it practically is: a cinchona plantation; and if the proprietor is able to persevere in his planting operations and is equally successful with ledgerianas and hybrids as he has been with succirubras and officinalis, he will ultimately have a property of immense value. The great point in this and other similar cases is that there should not be "devastation" of what is really capital for the sake of immediate returns.

SHAVING CINCHONAS AND COVERINGS.

Mr. Cameron does not believe in shaving more than once-a-year, in dry weather, and the trees to be invariably covered after shaving; the grass, if grass is used, to be *dry*. He would prefer jute sacking, coir matting, or cloth covering of a similar description, if it could be afforded in all cases, and if strips of bark are taken, as he has done with some of his succirubras, he regards covering with sacking or matting a *sine quâ non*. Mana grass, with its sharp edges, would cut into the exposed cambium and do great mischief. We saw some trees covered with paddy straw, but this substance Mr. Cameron emphatically condemns as liable to rot. So is mana grass, if left on in wet weather No doubt, shaving should take place at the commencement of the dry season or early in it, so that the bark may have time to renew and that the grass can be taken off before the advent of the fierce monsoon rains. Mr. Moens' original process was one of "whittling" of the bark, and this is what Mr. Cameron applies to his officinalis trees, which he would never spokeshave. Mr. Cameron shewed us specimens of original and renewed bark, whittled from his officinalis trees, and nothing could look better. We took away a few bits of each, and we suggested to Mr. Cameron what we hope he will carry out, that he should send a complete set of specimens of cinchona bark to the forthcoming Calcutta Exhibition. For officinalis bark and perhaps for succirubra, we should not be surprised to see him take first place in competition with the Nilgiri and Sikkim barks. * A considerable number of the succirubra trees, from which bark had never been taken, presented a very peculiar appearance as if ornamented with a mosaic, chiefly of diamond-shaped spots, elongated vertically. This was the result of the trees having been kept covered with moss for a period of eighteen months, and the strips of that bark, when removed, must be of great value. Mr. Cameron takes away only two strips, at opposite sides of the trees, and he never permits a tree to be shaved all round. In short while as anxious as other planters to obtain immediate returns, he is specially and we hold justifiably anxious not to sacrifice valuable and comparatively permanent capital, such as he possesses in his trees, to reckless harvesting in the present. Coppicing he especially deprecates, from his experience of the large proportion of coppiced trees which died on a neighbouring estate. On those which have survived, only one shoot is allowed to grow. Opinions and experience regarding coppicing differ, and many resort to a process which is certainly risky, in all cases, on the principle of, —"My poverty but not my will consents." Personally we owe Mr. Ewen Hay Cameron thanks for having afforded us the opportunity of seeing the results of one of the most successful experiments in cinchona culture in Ceylon, and those who wish to see the fever trees at their best as the result of intelligent treatment by one who carries zeal for the pursuit to enthusiasm, will find profit as well as pleasure in a visit to St. Regulus.

CINCHONA CULTURE IN JAVA.

(*Translated from Dutch newspapers for the "Straits Times."*)

"The scheme of selling by auction Ledgeriana chinchona seeds at the Government plantations here to British India planters, for whom they have more value than for those in Netherlands India, taking into account the fact that this variety of chinchona, the best existing, is most common here but is very rarely met with in British India, has justifiably drawn forth protests against it from all quarters. The scheme is objectionable in the interest of both the Government and the Java Cinchona planters. By carrying it out, the Government would be killing the goose which laid golden eggs. Every catty of these seeds distributed throughout Java represents a future Chinchona plantation yielding a permanent revenue, direct and indirect, to Government. Every catty of them forwarded to British India yields only a handful o coin. Scandalous misuse of the liberality of Government by a few of the planters here, who sold in foreign countries the seeds supplied them gratis for extending their plantations, has, in addition to the needs of the Treasury, caused the Government to hesitate on the good road hitherto followed. It strikes us that to prevent misuse of liberality, nothing would be more effectual than to give away seeds only on condition that if the latter cannot be accounted for by a certain number of seedlings in each nursery on a liberal percentage, the applicant will have to pay a high price for seeds not thus accounted for. So long as private estates do not yield seeds, and are neither extensive nor far apart, such control is not impracticable. We have since heard with pleasure that the scheme for selling cinchona seeds by auction has been postponed for the present."—*Batavia Dagblad*, 14th Feb.

Kola Nut.—Referring to the kola nut a writer says:—"It has been found to contain the same active principle, viz., caffeine, and more of it than the best coffee, and to contain also the same active principle as cocoa, but less fatty matter. Possessing the same qualities as these favourite beverages, it only needs proper treatment to develop a special flavour, and it would then probably be able to compete successfully with those beverages.—*Monthly Export Prices Current.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From LEWIS & PEAT'S London Price Current, March 1st, 1883.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White	Slightly softisb to good hard bright	£6 10s a £8
Yellow	Do. drossy & dark ditto	£5 a £6
CINCHONA BARK—		
Crown	Medium to fine Quill	2s a 4s per lb.
	Branch	1s 6d a 2s 6d
,, Red	Medium to good Quill	1s 9d a 3s

AGRICULTURAL DISTRESS IN BRITAIN AND PLANTING DEPRESSION IN CEYLON; NO REMEDY FOR ADVERSE SEASONS.

Though there may not be much consolation, there may be some instruction in the fact that we are not alone in our agricultural troubles. In the recent debate in Parliament on the Address, the prevailing distress of agriculturists in the Mother Country occupies a very prominent place; and is described as an urgent and painful subject. Sir W. Barttelot said:—"We have had eight bad seasons in succession, and are already threatened with a ninth. The prospect of the wheat crop is injured, stock is scanty and disease in some districts is rife." Mr Biddell was still more doleful, and said that "agriculture was as nearly as possible bankrupt." The London *Times* (weekly edition of 23rd February) referring to the debate, says:—"It is not surprising that the cry of agricultural distress should be loudly heard in Parliament, and that remedies of all kinds should be proposed. * * So *great* and so *universal* is the depression in *all* branches of agricultural industry that it is quite possible great changes may be impending in many parts of our agricultural system. * * The one certain and immediate cause of the present distress in undoubtedly, as all speakers admitted, to be found in the extraordinary succession of bad seasons from which this country has lately suffered." The general result of the debate was to "exhibit the deep uneasiness which prevails concerning agricultural distress. But though the fact itself admitted of no dispute, there was no practical agreement as to the proper remedies."

As we read this statement of the undisputed fact of agricultural distress in the old country, we seem to be reading a report of the condition of agriculture in our own island. The long persistence, universal prevalence and ruinous severity of failure seem to be alike in both countries, as well as the perplexity as to *remedy*. The *Times* indeed, seems to anticipate great changes in the present system of agriculture as a result of this long period of depression.

There may not be material consolation in the fact that we are but bearing our share of a common misfortune, but we may perhaps derive as we have said some instruction from it. Let us then mark the identity of the period through which our misfortunes have existed. The eight successive years above mentioned take us back to 1874, when the planters of Ceylon had also good harvests as well as agriculturists at home. But that year was exceptional both here and in Europe. Mr. Caird writing in 1879 of the previous decade, said there had been only one good crop, that of 1874, since 1870. Thus we are carried back, curiously enough to the date when the local failure of coffee crops commenced. Exceptionally high prices, happily for us, mitigated the severity and postponed the culmination of our suffering; still, the fact remains that the providential stroke fell here and elsewhere at the same time, and has persisted-alas! with but little interruption through the same protracted term.

In the absence of leaf disease, or any other specific pest, to which to attribute the disturbed condition of home agriculture, we see a perfect agreement of opinion expressed as to the cause of the distress, namely, *adverse seasons*; and if that comprehensive term be so used as to embrace all the forces of nature, known and unknown, it may serve as a confession of our ignorance, but does not enlighten our minds. It may furnish an answer to the general inquiry as to the cause of our discomfiture, but it makes the answer evasive, and in no wise relieves our perplexity. It may serve to stave off further question, but is it wise to adopt an answer to so great a question which satisfies the ear and tends to stifle research?

In truth we know very imperfectly the operations of the recognized factors which combine to produce the complicated phenomena of life and vegetation; and there are doubtless *others* besides whose existence we only suspect to account for effects not referable to known causes. Of the nature and operation of these, of course, we know nothing; but do we simplify matters by ignoring them and merging all the active influences of nature in one rather evasive term? Our studies of rainfall, wind, heat, and other known elements of that inscrutable term, season, though pursued with the aid of the most elaborate records, conveniently tabulated, still too often leave us in hopeless perplexity. Inferences which, after immense pains, we seem to have almost established, dissolve one after another, and we are driven baffled from the pursuit, with little better result, it may be than a headache. In truth, the research is hopeless, so long as we seek to resolve a problem of many factors by a partial and imperfect investigation and comparison of a few. The records of our thermometers, rain-ganges, barometers, &c., are undoubtedly of great importance, but what light do they throw on the mighty solar forces exerted by the agency of direct sunshine,—by the strange and devious actinic ray, with its incalculable chemical force—by the forces which accompany the phenomena of sunspots? We know that all these mighty forces exist and operate powerfully in the living organisms about us, but, as yet, we know not the part they play, nor distinguish the effects they produce from those of forces we recognize and examine. What strange force is that which suddenly endows with life and activity the myriads of germs which, till so kindled, lie for indefinite periods of time in a latent state? What, for instance, brings forth locusts, as it were out of the dust; aphides and fungi covering the whole surface of vegetation as though they had sprung out of its tissues as an exudation; and also, a fearful brood of pestilent germs which sweep over the earth like an atmosphere of animated death-warrants served on poor helpless humanity. (*Helpless*, however, only whilst *ignorant*.) What may be the nature, and whence the origin of those forces we know not. Neither rain-gauges nor other of our instruments of research afford us any clue. But we shall not be acting wisely if we put them out of the account and lump them all in a term which we would thus render vague and misleading.

Whilst deprecating the unscientific use by home legislators of the term in attributing the general disturbance of agriculture solely to adverse "seasons," we nevertheless commend the soundness of their conclusion in thus referring our misfortunes to Providence. Define it as we may, season comes not within the control of man, but is the act of God in the working of His immutable laws. The speakers in the parliamentary debate to which we refer addressed a sympathetic audience in terms of deepest sympathy. No attempt was made to wrest the facts of the universal distress for the support of favourite theories, or for party purposes. The hand of the Omnipotent was, by unanimous agreement, recognized. No railing accusation against their fellowmen by sufferers there! It is in Ceylon alone that men are found vile enough to overlook the Divine power which has been at work,

and to refer our suffering to "folly, deceit, inflation, exaggeration," and such like impotent causes. Though unanimous in Parliament as to the cause of the prevailing agricultural distress, and in the desire to obtain some remedy, there was no agreement as to the remedies proposed. What wonder: a remedy for seasons—a remedy for the immutable laws of the universe? No: our hope must be in acquiring a knowledge of those laws.

Recent research has shown that the measure of *direct* sunshine, as compared with veiled or interrupted light is a potent factor in the vegetative processes, especially in those of *fruition*. The comparisons instituted in our columns yesterday between temperature recorded in Bogawantalawa and that in Lindula, illustrate the fact that all our other records of the weather are fatally incomplete until this one be comprehended amongst them. Here is a point to be gained, and probably a more important one than most of those we have hitherto bestowed our pains upon. It has recently been shown that electric light will, for a time, at least, support vegetation, but fails utterly to promote fruition. Here again is a suggestive fact. There are others which might be brought forward, but enough has been said to shew the importance of the field for observation and research thus opened up—an importance not lessened by the hope that we may shortly be favoured with a cycle of seasons as favourable to the planters of Ceylon and the farmers of Britain as the past series referred to, has been the reverse.

PLANTING ON THE HILLS OF CEYLON.

LEDGERIANAS ON YARROW.

I quote information which will be interesting and useful to readers of the *Tropical Agriculturist*:—

"Yarrow, Pussellawa, March 24th, 1883.

"It has struck me that it would be advantageous to cinchona growers generally if you would kindly personally look at the remarkably fine ledgeriana trees growing on Yarrow, as also the very successful nurseries of plants and seedlings established from carefully selected seed.

"There appears to be a general belief that ledger plants raised from seed cannot be relied upon to come up true to type: however true this may be in regard to imported seed, our experience certainly is that with seed carefully harvested from selected trees of the true ledger type the plants may be relied upon to come up true to type.

"It would also I think be well worth your while to inspect the clearings we have successfully opened of ledgers raised from Gammie's seed, the plants in which are growing vigorously and certainly dispel the current idea, as to the delicate constitution of this variety and the difficulty of growing it. I may here mention that these clearings have received no greater care or attention than would have been bestowed on the supposed hardier varieties, not even being staked during either of the monsoons. In spite of this I think it may safely be stated that it would be difficult to find either in this or any other district finer clearings of the same age of any other variety.

"Where elevation and climatic conditions are favorable and soil of an open nature, there seems little doubt of ledger growing freely and yielding the best results. Mr. Laurie, the part proprietor and superintendent of Yarrow had occasion a few weeks ago to cut out a 5½ year old ledger tree: the result in *dry* bark (root, stem and branch) is 10 lb—this certainly is a most encouraging return. The tree in question was a well-grown one, but even with a lower average, which might be expected from a large number of trees, the return would still be most remunerative considering the high value of the bark.

"With regard to *nurseries*—a general impression appears to prevail that ledger seed is much more difficult to propagate than seed of other varieties. As a matter of fact in no year have our nurseries been so successful in point of outturn as during the past, when ledger seed was almost exclusively planted, the tendency certainly is to over-coddle plants raised from seed of this valuable variety, and many failures may be traced to this cause, whereas, in cases when the seed has received the same treatment as the commoner varieties, the results have been eminently satisfactory.

"What do you think of the accompanying piece of ledger bark from a 5½ year old tree?"

We are naturally gratified to have such strong confirmation of our opinion that plants from ledgeriana seed will generally come true to type, and as to the successful growth of the trees the desiderata clearly are good climatic conditions and (above all) free soil.

A SPLENDID SPECIMEN OF BARK FROM A 5½ YEAR OLD TREE

Most of our readers are aware that not only is the bark of ledgeriana rich in alkaloids but large in substance: thicker even than succirubra bark. Knowing this, I was, nevertheless, taken by surprize by the specimen sent me of the 10 lb. dry bark taken from a 5½ year old tree at Yarrow. (at 5s per lb. that would mean £2 10s realized from one tree!) There were three planters present when the packet was opened, and they all insisted that the inner portion of what was claimed to be bark was really wood. But, ligneous as it looked, I said: "No, not wood; cambium," and sure enough when pieces of the supposed wood were cut away and masticated they gave out a bitter so intense as to leave no further doubt of their *bona fides*. My thought of the bark, therefore, is that it is splendid, and I hope yet to follow Wordsworth by singing of Yarrow not only visited but revisited. The experience obtained on this estate in Pussellawa, by Mr. Wm. Smith at Mattakelly, and by Mr. E. H. Cameron at St. Regulus—not to mention other cases,—is conclusive in favour of good seed of the most valuable of the cinchonas succeeding well in nurseries and the resulting plants growing well in the field, where conditions of climate and soil are favourable. Where pure ledgerianas will not grow well, hybrids will probably succeed, including those resulting from a union of succirubra, of which I saw some during my recent journey, which resemble those on this estate in luxuriance of foliage and robustness of growth.—In this, which will probably be my closing letter "From the Hills" on this occasion, I think readers of the *Observer* will acknowledge there is a good deal of interesting and valuable information on cinchonas and their culture: thanks to correspondents and friends.

THE DWARF BAMBOO AS A COVERING FOR SHAVED CINCHONAS.

Has any cinchona grower tried the dwarf upland bamboo as a covering for shaved trees, and with what result? The leaves will, no doubt, rapidly wither and drop off, but the stems can be thickly laid on.

TEA AND SHELVES.

An Assam planter of a good deal of experience, a visitor to Ceylon, accompanied me in a walk over our tea-fields, and expressed pleasure and surprize to see such growth at such an elevation and on such steep features As regards the soil, he agreed with previous visitors as to its excellence. He was equally pleased with our tea-house arrangements, especially the multiplying of leaf-withering space by means of shelves (wooden frames covered with cloth) held up, one above the other, by the simple device of a knotted rope. That idea for utilizing space he will carry back as a present from Ceylon, the youngest of Indian tea districts, to Assam, the oldest. As I write, at 1 p.m., the rain, which commenced about half an hour ago, is pouring. What its effect on coffee may be remains to be seen, but, as there is no blossom out now, it will probably be as beneficial to coffee as it certainly will be to tea and cinchonas.

SHAVING OF CINCHONAS.

By the way a planter I met yesterday spoke strongly in favour of commencing to shave cinchonas at an early age, contending that, if allowed to grow to six or seven years before being operated on, growth will be arrested by the shock; while trees shaved at half the age continue to grow, frequently repeated shavings not stopping them. Thus do opinions differ.

THE CULTIVATION OF CINCHONA (MORE PARTICULARLY *C. OFFICINALIS*) IN THE YOUNG HIGH DISTRICTS.

Some time ago, when there was a discussion on the marvellous differences between clearings situated almost alongside of each other in the high districts, an experienced planter wrote to us as follows in a letter laid aside at the time :—

————, and especially those portions of it where officinalis is flourishing most luxuriantly, was some 2 years to 3 years ago chiefly remarkable for its red appearance, the steepness and elevated position of the fields referred to making it a very conspicuous object for some miles around. This objectionable colour, however, has now been replaced by the rich green of thousands of officinalis trees, and by the paler but brighter line of the succirubra. I do not refer to the older cinchona clearings on the estate, for they have always been green since the trees were 2 years old. The soil is not what would be considered rich, but it is of a free loamy nature with a considerable admixture of sand in places. It is well sheltered, and the annual rainfall is from 70 to 80 inches. The older officinalis clearing is situated in a basin, the land gently sloping to an almost flat centre, and the trees are equally large and healthy over *the whole area* of the hollow. An "abandoned plantation" is on the opposite side of the valley, having a different aspect and rainfall, and some 5 miles distant from ————. A casual glance at the soil of the two estates would be quite sufficient for the most inexperienced person to form his opinion of the respective merits of the two places, apart from considerations of aspect, climate, position and elevation. The one runs from 5,000 feet to 6,000 feet. The "abandoned plantation" does not reach 6,000 feet. It is, I believe, impossible to arrive at any satisfactory conclusion, as to why some estates are more suitable for the cultivation of officinalis than others are, but I have noticed one fact in connection with this : and that is that on most of the places adjoining the patanas officinalis is doing well, whereas on the other side of the valley an even cover of this variety is almost unknown. Yet, on the other hand almost adjoining the "abandoned plantation" is a place where there are many thousands of very fine 4-year old trees, and on land very near there is a very good and even 2-year old clearing. The more one tries to arrive at the "reason why," the further one gets afield. I believe, that recently opened land is often too wet, and that the action of sun and air upon it will eventually make it very good cinchona land, and I see no reason why replanting should not be carried out on land where plants and trees have died, provided, of course, that one takes care to avoid really stiff clayey places. Close draining and one dry season will, I think, go a long way towards preparing damp soil for cinchona.

My theory with regard to officinalis, though it may be a very wrong one is, that our forcing climate establishes a growth which, from the poverty and unfavourable condition of our soils, the roots cannot keep pace with. To remedy this I am trying topping 1 and 2-year old officinalis trees at 3 to 4 feet. This throws strength into the roots, and I have seen it *arrest* canker. I cannot yet say *cure* it, as I must allow more time before I can speak positively.

I do not attach MUCH value to a light rainfall, as I know two other places equally favoured in this respect (if it *is* an advantage), and yet officinalis has died out there in a most heartrending manner.

(*A month later.*)

This much I can say with regard to the above, that *some* officinalis trees which looked quite unable to prolong a miserable and hungry existence a month longer, have from being topped at about 4 ft. 6 in. thrown out a bunch of healthy suckers and have filled out in the stem considerably, but, on the other hand, some of those I topped have died.

I have very little to add to what I wrote to you about the cinchona on —— and ——. The former place continues to improve steadily, while the reverse is I believe the case with the latter place : but, as I said before, there is vast difference in soil, climate and rainfall between the two places. From what I have observed in the Bogawantalawa valley I should say that officinalis will grow very fairly well from North Cove along the slopes of the ridge dividing Bogawantalawa from the Bopatalawa patanas down to the top of Killarney, at which latter place there is a good clearing rising 3 years. On the other side of the patanas Waverley and Sutton are remarkably good and Holmwood also, where the pesty and clayey soil of the flats and shallows is absent. The soil all over the area I have referred to above is of a very light, dry and gravelly nature and the rainfall is light.

There is, however, in my opinion one essential to success in growing cinchona officinalis, and that is seed from old and healthy trees. Given every advantage of soil, shelter, climate and elevation, I do not think a successful clearing could be made with plants raised from seed of young and unhealthy trees. In 1880 June-July I opened 20 acres ; planted it 3 feet + 3 feet with plants raised from the seed of very old trees on Manickwattie, and I am convinced that there are at this moment at least 4,000 trees growing on every acre of the clearing. In 1882, October and November, I planted 10 acres adjoining the above with plants raised from seed from young trees 4 to 5 years old, and not 10 per cent of them are alive. I admit I was more favored with regard to weather when planting the older clearing, but the difference was not great enough to cause such a contrast.

I have noticed in one of my officinalis clearings that the only portion of it alive is a small piece regularly nibbled off by elk, and in this piece *there is hardly a vacancy*, but the 2-year old plants are merely bunches of suckers from 2 feet to 3 feet high.

Sulphur liberally sprinkled in seed beds where the young seedlings are dying off is a *certain cure*, as I have proved over and over again. It should be sprinkled some 4 inches beyond the outside of the dying circle.

PLANTING NOTES ON THE STRAITS SETTLEMENTS.

No. 4.—BY H. COTTAM.

PIONEERING IN PERAK—THE INFLUENCE OF CLIMATES ON ONE'S IDEAS—CECILIA TEA CLEARING—CHINESE NEIGHBOURS—OPIUM EATING AND TALKING ALL NIGHT—MALAYS IN THE CLEARING LINING—THE HABIT OF SMOKING CIGARETTES AMONGST THE MALAYS—OUR RUSTIC FLOWER GARDEN—CHINAMEN, MALAYS AND KLINGS (TAMILS)—RAINFALL—FEVER AND HARD TIMES—A KNOWING ELEPHANT AND STILL MORE KNOWING MONKEYS—ELEPHANT TRAVELLING—JOURNEYS TO WATERLOO :—AMATEUR BAKING—CENTIPEDES—THE CHINESE NEW YEAR IN PERAK.

A letter from Ceylon just to hand from a planter and old friend in the Madulsema district reminds me that my letter No. 1 addressed to you contrasted very favourably to my

private letter to him. Now the only way to account for this is difference of climate, temperature high, and high smells from the neighbouring Chinese villages.

The plain truth of the matter is this:—To catch the rainy season it was necessary to descend from the mountain top 3,500 feet above the sea to a clearing only about 1,200 feet elevation. Added to this, the neat little shaded well we had cut for our people there was in a filthy state and the water unfit to drink or even wash in, all the accumulated dirt from the Chinese and Malay compounds being washed down into their drinking water. Millions of mosquitoes of the ring-tail variety disputed our right to camp at these diggings and simply mobbed a poor fellow at certain hours of the twenty-four, keeping up a perpetual tune on their little musical instrument (a cross between the Scotch bagpipe and a Jew's harp). Any way they harped on the same old string all night and drove their poisonous probosces (if we may use the expression) into every part of our unfortunate bodies covered or uncovered. It took the bloodthirsty little vagabonds some time to find your humble servant, because they evidently mistook me for a Chinaman, and jumped at the conclusion that I smoked tobacco and that of doubtful quality, little dreaming, deluded little insects (God bless them!), that I was fresh from the hill, with blood in good order and offered no obstacle to their taking me in the flank or even entering in a body by the door or window made of Bertam leaves and without the fear of being smoked out (the writer only indulging in a meditative smoke of one cheroot after breakfast and one after dinner). However the mosquitoes remained outside for several days, thank goodness, though they "made for me" properly every time I went out for a walk or to speak to the Chinese or Malays in the evening.

The Malays seemed to get the lion's share of their attention, and scratched themselves into ugly sores all over their bodies, and their blood not being very rich harbours the poisonous bite and festers into deep-seated ulcers: they complain bitterly of the "Namoo" or mosquito. Partly owing to their bodies itching and perhaps through a bad night's rest, the Malays worked very carelessly in the clearing, engaged as they were in lining for holes 10 by 10 for Liberian coffee. One of them would creep along at a snail's pace with the lining rope until he reached the place to stop and stretch the line, whereupon he immediately produced a cigarette and squatting down on his hind legs began to smoke, looking as though he did n't care to call the Queen his aunt—so contented and happy a cuss.

I made a rough calculation that from the smallest boy to the most ancient individual they smoked about twenty cigarettes on an average. It was several days before I could check the bad habit, but now the Malays seldom smoke in my presence. Yet the cigarette may always be seen lurking behind the ear of every Malay man or boy ready when the "Tuan" (master) is not looking. But with all the faults of the Malays I love them well. They are a much better people than generally represented to be by people who do not know them well. I shall therefore devote a whole letter to them in this series in reply and as a counterblast to a letter written from Perak some time ago, and which, being *so untrue*, disgusted and annoyed the majority of the Europeans in Perak, especially old settlers who have had Malay servants for years and where mutual love and respect exist.

The Hill-Malays are very clever at running up a shanty in the jungle, and the one I occasionally live in is very snug, made entirely of jungle sticks and plaited leaves of the Bertam. Heavy rain descended but none came in. The floor is made of bamboo and strips of bark, and not a nail is used in the whole construction, rattan cane always being used as a substitute for nails, in other words strongly tied.

Their own huts are of the same pattern, built on piles driven into the ground. The floor of a Malay hut is rather more open to enable them to smoke *ad libitum* and spit as much as they like, and empty their rice water away without the trouble of opening the door. For protection from wild animals at night (tigers have often entered houses and carried off human beings and domestic animals and do so still *in many* parts of the peninsula) the arrangement of an elevated floor is safe and secure, and, as before remarked, they prefer an open floor to let the rubbish go through to climbing up and down the stairs or wooden ladder.

This new clearing, called "Cecilia" and named after one of the daughters of His Excellency Sir Frederick Weld Governor of the Straits Settlements, is a pretty formation or lay of land, and I managed to trace three good bridle-paths through the clearing with the aid of one of Walker's tracing machines procured by the Perak Government. These roads improve the appearance of the Cecilia estate immensely. There are a few acres of flat ground suitable for a site for building a bungalow, outhouses, and sheds for a farmyard, with grass field and paddock for horses, cows, sheep, pigs, and poultry. The water supply is the difficulty, but this may be conquered by spouting water from a considerable distance from the hill ranges above, or cutting drains for the same purpose to economize galvanized iron spouting, which is very expensive and difficult of transport.

All flowers grow well here, for we amuse ourselves every evening (stop a bit! I 'm not quite sure about the kling being amused) making rustic little gardens under the shade of large jungle trees, blending some of the rare plants of the forest with domestic flowers, such as the carnation and pink, crotons of kinds, calladiums, both wild and cultivated varieties (including the black one), belfry, and a lovely climber, white and scarlet, cockscombs of rare beauty, asters, zinias, begonias, sweet william, phlox drummondii, coleus variegated, and dark purple grows freely. crocuses, pink and white, gladiolas, crinums, scarlet, and lilies, &c.

Amongst other pretty things collected in the Perak jungles is a large pink or orange flowering shrub called the ixora, I believe. If this was mentioned in a previous letter, I won't apologize, for repetition can do no harm in this case.

Tiger-striped wild ginger, resembling the maranta zebrina common in Ceylon and a plant the Princess of Wales is very fond of, judging from the photographs of the Princess.

What should we all do in this world of ours, where we cannot "reject the weeds and keep the flowers," making a "heaven on earth," as Tom Moore would have liked, were it not for the pleasures of gardening and reading? They are certainly the writer's two hobbies, but often very difficult to ride: for instance, when more land is opened than can be kept in order, the coffee, tea and cinchona nurseries require all the available labour to keep them in order, or heavy loss would be sustained. Flowers and rare plants are then called rubbish by some people and in dry weather even grudged a drink of water! Then again, reading is not always practicable, for what with a row in the kitchen between the cook and Johnny Amo the boy, with Ha Sing the water-carrier throwing in his opinion; an argument between the kopala or head Chinaman about advances on a road contract, and the China sawyers kicking up another bobbery, whilst the Malays have got a long yarn under weigh in a shanty under my nose and at pointed parts of the story yells of laughter rend the air and echo among the rocks; a small gambling party in the next hut, and in another corner a difference of opinion between Ha Koon and Ha Toon about a fowl mysteriously disappearing: with opium smokers just turned out when they ought to be turning in, make up a sum total of the most infernal rows ever heard or ever invented to upset the nerves of a European, kept up religiously until the small hours of the morning, when the wretches drop off one by one from sheer exhaustion and go to sleep about the time that people in health should be getting up and going to work. When they do turn out next morning they look as though they wished they had never been born and that living in this world was a gigantic mistake, mooning along with a stinking old bamboo pipe in the mouth and a big straw hat on the head, wide trousers of blue or black and sometimes clattering wooden shoes, heavy eyelids and generally an up-all-night-hat-caved-in-dissipated-good-for-nothing-looking-son-of-a-sea-cook.

The rains were heavy and continuous, and, though slowly, yet surely, the Chinese finished their clearing contract and took up the cutting of the roads traced.

Meanwhile one of our klings fell ill of fever, and before quinine could be obtained died. This was a loss to me, for poor Valau was teaching me the Malay language by interpreting in Malabar or Tamil. After the death of Valau, the other kling, a very old-fashioned individual, bolted without his clothes. So we took the liberty of using one of his comboys or sarongs to make a winding-sheet for Valau. Half-a-dozen Malays willingly dug a six-foot grave for the deceased cooly and about mid-day carried him to hi

long home, his durai being the only mourner, though the Malay headman remarked that he hoped somebody would give him as good a funeral when his turn came.

Being now without an intrepreter, and my knowledge of Malay very limited, for I had only been 6 weeks or two months in Perak, there was difficulty in making myself understood, and Mr. Bozzolo kindly relieved me, he coming down to Cecilia and I returning to the mountain top bungalow. I believe Mr. B. made short work of the Chinese and soon put a stop to the nocturnal row they made by chasing them round with a long bamboo, and, as they owed the Government money for advances on contracts for the jungle felling and clearing, a holing contract was given them to clear themselves and then clear out altogether!

Suffice it to say, at the expense of his health, for several bad attacks of fever laid him low, Mr. B. succeeded in getting the Cecilia clearing planted before the rains were over about Christmas time.

The climate here is very similar to that of Ceylon: 3 months of wet weather in October, November, and December, squally weather at the change of monsoons in the middle of the year, and the rest as dry and hot as —as—well—as a baker's oven!

It may interest some of your "clerks of the weather," who take an interest in meteorological returns, to see the rainfall for the past wet season in Perak, so herewith a copy of the register on our Government Hill Garden:—

Meteorological returns for Nov.-Dec. 1882 and Jan. 1883 of the Government Experimental Mountain Gardens, Perak. Elevation 3,500 ft.

	Ther. in the shade.	
	Inches.	Average Temp.
1882.—Total rainfall for Nov.	16·79	70°
1882.— ,, ,, ,, Dec.	6·66	70°
1883.— ,, ,, ,, Jan.	1·42	74°
Total	24·87	

Both December and January fell short of the average rainfall of past years in Perak. October returns were sent to the Government Office.

N.B.—Though the December rainfall only amounted to 6·66 the days were cloudy and we had good planting weather, which was much better than heavy plumps of rain, there being few breaks in the working days.

On the 2nd Feb. (this month) we got 1·74, on the 6th 42 points, and 5 points on the 7th Feb.

You will see that January was very deficient in rain, and our newly planted supplies suffered to some extent in consequence on the hill, though on Cecilia, where the forest was only recently felled virgin forest, everything put down is growing remarkably well, and promises to be a successful clearing for tea and coffee of both Liberica and Arabica as well as fruit-trees and rubbers, &c., &c.

Although more fortunate than Mr. B. in escaping fever nevertheless I began to feel out of sorts, and used an Englishman's privilege pretty freely by "growling like a bear with a sore-head" at everything and anything—a sure sign of the liver being out of order. When in this state a letter from Captain Schutze generally arrived by a kling, inviting me to spend the following Sunday at Waterloo, and this of course was duly accepted, the pony, which we named "the Duke of Wellington," being in readiness at the lower bungalow. The ride to Waterloo was not "beer and skittles," however, for the "Iron Duke" was very troublesome and lazy at times and bad at going downhill, and if I dismounted he expressed objections to my getting up again, and then when everything was going on smoothly and the rider began to hum a tune in contentment whilst passing through a natural botanic garden (for such is the virgin forest of Perak), the Duke would come to a dead stand-still before a giant of the forest 15 or 16 feet in circumference lying prostrate across the bridle path, and all this time the heavy rain falling in a most pitiless fashion on horse and rider.

A climb up Jacob's ladder brought me to the Waterloo bungalow, tired and wet through, and the "gin-sling," already on the verandah table, for our especial benefit, was very acceptable, the distance travelled being about 14 miles, more than half of which distance walked, and breakfast nowhere, except perhaps a bottle of beer and a Chinese rusk at the tamby's caddy on the Kwala Kangsa road to Gapis

On another occasion we made a journey to Waterloo walking eight miles down our own hill to the lower garden on the banks of the Kangsa river, and mounted the female elephant, who carried us along Lady Weld's road and on towards "Romah Papan" to the turn off at Sara Liberian coffee garden without mishap, but when descending the steep jungle path rounding the picturesque Limestone-hill before referred to, she began to show signs of unwillingness to go on any further. Capt. E. had dismounted and Mr. Yare got up in his stead, but our combined weights only amounted to about 300 lb., or say three hundredweights, not at all a heavy load for an elephant (although a female). I remarked that her ladyship was very lazy, whereupon Mr. Yare gave her a gentle kick at the back of the left ear and she accordingly went a little faster, but on arrival at a dirty pool of water sucked up a considerable quantity of gray, muddy, luke-warm water and throwing her trunk high in the air gave *me* the *full benefit* of a warm bath, smothering my shirt front and blue cloth coat with mud and filthy smelling stagnant water. This was quite an unexpected unadulterated christening and so careless was this young woman in rounding corners where the road was a gradient of about 1 in 6 and in passing by projecting branches of trees by the roadside that we thought it prudent to perform the rest of our journey on foot, getting wet as usual before reaching the Waterloo bungalow. However, it is a long jungle path that has no short cut, and on arrival a bath and change of clothes with refreshment soon made us forget the unpleasantness of jungle travelling in the rainy season in Perak.

The young ladies treated us to select music, and every luxury that could be wished for was obtainable at Captain Schutze's hospitable board. A full description of this estate was given in letter 3. So we need say no more than what has been before stated that it is a fine property, beautifully situated and the bungalow very comfortable. Amongst other amusements in the drawing-room is an organ mounted by four figures, one of them a monkey in full dress playing the violin, whilst another gentleman collects the half-peuce, though, should anybody play him a practical joke by putting anything foreign to money into the plate, he deliberately throws it back to the donor. Another holds a bottle in one hand and goblet in the other and drinks to the visitors, and the fourth is an ancient individual who twists a golden serpent round a pole. All of them shake their heads in a knowing manner and roll their eyes, making up a very comical and amusing exhibition ("all for a penny").

Unfortunately the Schutze family took their departure from Perak to Singapore last Christmas, and Mr. Wambeek from Ceylon is in charge. Poor fellow he must have a lonely time of it by himself. There are no planting neighbours between this and Kwala Kangsa on the one side and Thaipeng on the other: both towns very far away. Perak is certainly very thinly populated and the monkeys seem to hold possession of thousands of acres that might be under cultivation. It seems a desolate country at times and requiresa stout heart to make oneself feel at home in such a wilderness. Poor Taylor isdown with liver in Penang and his good wife and family with him and it is feared he will not be allowed to return to his duties. I believe Mr. B. has gone to see them off to England, if fit to be removed from his sick bed. The state of Perak loses the services of an able and energetic officer of long and steady service. He was in charge of the armed police-force at Kwala Kangsa, the Resident's quarters.

When at K. K. Mrs. T. kindly supplied us with bread on the hill, but since Christmas we had to depend entirely on Huntly & Palmer's. Sometimes running out of biscuits, we then tried a bag of flour and a bottle of baking-powder, and Mr. B. purchased a "Mistress" stove. The writer turned baker and the first loaf was a success, being made with milk. The next loaf not so good, being heavy and causing dreams of murder and fire, two-edged swords, snakes, centipedes, and other dreadful things.

The last-named *insect* comes down from the roof regularly every evening when the duplex lamp is put on the dining table. Great big ones sometimes come flop on the table, and one night a centipede stung me on the pulse vein and threw me into a fever all night, dreaming that another was inside the bed and had stung my left leg! On New Year's night a big fellow dropped into my plate,

so being the festive time of the year I gave him a drink of *** three star brandy and pushed him into it—altogether like a certain Duke in English history in the butt of Malmsey.

Mr. Denison, the superintendent of Lower Perak, when here with the Resident, had a young one drop into his finger-glass and wriggle about like a young alligator. There are half-a-dozen good specimens in the bottle of ***, but their fate does not deter the others from exploring the dinner table, for there was one asleep on a ripe pineapple only last night in the middle of the dinner things.

By the bye we made our own tea, and a very strong brew it was too, everything done in the orthodox manner, gathering, withering, rolling, fermenting and firing, the choolah or furnace being an old kerosine drum similar to the Deyenewatte apparatus in Badulla. It was certainly killing 3 birds with one stone, a loaf of home-made bread and a gooseberry tart in the oven and panning tea outside.

The "Mistress" stove has now found its way into the kitchen, and Johnny China makes the bread as hard as bricks.

I believe the Revala Kwala Europeans got their staff-of-life from Thaipeng, 18 or 20 miles off, in the mail-bags, but the postman objected to the great weight of the letters and newspapers as the community increased in number.

On Mr. B.'s return from Penang I shall have to camp at Cecilia clearing again to connect the roads already cut and trace some more. I hope the mosquitoes will not find me out until the job is finished. The heat is great, too, at this time.

A notice in the *Straits Times* appeared lately of the marriage of Mr. Woodgate, formerly our neighbour in the Madulsima district. He was also advertising for a field assistant, both circumstances good signs of prosperity. He is a fledged surveyor in Malacca somewhere.

With a few Malays we are transplanting and pricking out Ledgeriana plants, with klings gathering coffee and pruning tea bushes, another gang cementing the bath room floors, and Chinese carpenters making an office and storeroom.

Life here is pleasant enough when backed up by labour, never mind how many different nationalities come to work. But when nobody comes, the feeling is very much akin to running amok!

Today and yesterday the Chinese commenced their New Year and their great ambition seems to be to see how many they can stow away and how much noise they can make with their Chinese crackers for chin-chin joss.

Little Hongkong lets bang a volley from the sawyer's lines on the ridge, and immediately big Shanghai opens fire in return from the road contractor's quarters at the foot of the hill.

Kwala Kangsa looked in the darkness from a bird's-eye-view like London (on a very small scale) with its numerous feasts of lanterns on the bank of the Perak River or Thames of the Peninsula.

LOWCOUNTRY PRODUCTS.

(*From a planter on his travells.*)

LIBERIAN COFFEE.

I have only seen the books of one estate in Kalutara, and they shewed that the 3-4 year old clearing is bearing now at the rate of over 5 cwt. per acre, planted 10 feet by 10 feet, or nearly 11 cwt. per acre at 7 feet by 7 feet; and this estimate is nearly picked now, the balance being certain, which goes more strongly than words to refute Mr. Ferdinands' opinion and statements.

Any of your readers who is disheartened with present gloomy prospects, or better still you yourself, Mr. Editor cannot do better than take a trip into one of the New Products districts, and refresh your eyes and heart with the results of the past five years' work, and the present prospects of most estates.

LEAF-DISEASE ON LIBERIAN COFFEE: BIG CROPS.

I have been told that leaf-disease would shortly kill out Liberian coffee, and indeed an idea of of this kind has become rather general lately, I think, but on this estate we find the trees, which have lately had an attack of leaf-disease, ripening up a fine crop of coffee, till on this small property of about 180 acres (30 of which are young and scarcely contribute anything) Mr. Jardine's estimate of 3,500 bushels parchment is certain, and he believes that 4,000 will be got in, if not more. To date about 2,000 bushels parchment have been dispatched, while the trees are still laden with crop, and a very fine blossom has just set equal to at least 2,000 bushels. This is the first big blossom of 1883, and is fully as early as last year's, and from the appearance of the coffee, which is vigorous and healthy now, one can easily understand that Mr. Jardine's forecast of next year's crop, 6,000 bushels parchment, is very likely to be got.

COST OF CULTIVATION OF LIBERIAN COFFEE AND COCOA.

Leaf-disease may attack the coffee—it does, but planters have made up their mind to see it more or less everywhere nowadays; and the desideratum of the coffee planter is not coffee free from leaf-disease, but crop!—no matter what the condition of the trees is, and coffee bearing and blossoming as this is doing is certainly pretty near what is wanted. Its healthy appearance at present, under the crop, is sufficient to justify our believing that it will live for a number of years, and give returns which will make it a handsome investment. On the 150 acres in bearing the crop is over all equal to 5 cwt. per acre, but if we take the oldest field it is at present giving about 10 cwt. per acre, and taking into account that it was very widely planted—more than double the width Liberian coffee is being planted nowadays †—you will easily understand what a crop the trees are just ripening. The pulping-house is small, but railway transport makes up for this, as Mr. Jardine dispatches his coffee straight from the cisterns (wet) to the station, and it arrives in Colombo in perfect condition, to be dried and sorted there. The pulper was cutting a few of the leaf-diseased cherries, but not very many, and on a good sample of cherry this pulper, a Walker's disc, makes very good work, and it will, no doubt, be improved upon yet, when the picking over of the tails, which has to be done at present, will be unnecessary.

The coolies were picking three bushels cherry on the occasion of my visit, reminding one of bumper crops up-country, in days of old.

Liberian coffee and cocoa can now be carefully brought into bearing for R120 to R150 per acre, including purchase money for land; but in the days when Liberian coffee plants cost 25 cents each, only 4 years ago, it was a very different matter, and I know of an estate in another district, which, with plants, &c., cost about R350 per acre the first year.

In order to provide against contingences, and assure the stability of the investment in the future, the proprietors have had cocoa interspersed throughout the coffee, and in one field the cocoa I saw about 18 months ago a very doubtful success is now rearing its head above the coffee, in beautiful avenues, while clusters of ripe pods all over prove that it has found a suitable habitat. A few cwts of cocoa have already been dispatched, and prices obtained for it, R50 to R55 per cwt, augur well for the future.

VARIETIES OF COCOA.

There are on this estate in one small field a large number of varieties of cocoa, but, so far, the market value of these varieties has not yet been ascertained.

The pods (mostly yellow) on some trees are very large, and a cwt. of clean cocoa is obtained from two-thirds of the number required in the common variety. Mr. Jardine is at present in communication with Dr. Trimen, with a view of finding out if any of the other varieties are now considered better than the ordinary one from the botanist's point of view, and when Dr. Trimen has given a definite answer in a regard to them Mr. Jardine will probably give the public through your columns the benefit of it.

EXPERIMENTS WITH WEEDS.

The whole estate will this year be planted with cocoa between the lines of coffee at different distances apart. A small plot of coffee has been left unweeded except removal of jungle staff, as an experiment. It has been over a year unweeded and the coffee shows no difference from the surrounding field. Lately however a small grass weed has appeared, which Mr. Jardine fears will damage the coffee much when it spreads, if left; and it will be interesting to know if it does so after a while: this I have no doubt Mr. Jardine will let us know, in due course, through your columns.

PEPPER VINES GROWN ON TO JAK-TREE BREAKWINDS.

Jak plants have been put in all over the estate as breakwinds, and for slight shade, and on the stems of them pepper vines are to be trained; a small experiment in growing pepper already having succeeded very well indeed. I noticed little or no damage to coffee trees growing close to Ceara rubbers, but perhaps in time they may be injurious to the coffee and cocoa in their vicinity.

FRUIT TREES.

Anon we retrace our steps to the bungalow, and during the short "gloamin," have just time to inspect a large number of fruit trees which the careful superintendent has planted all round the bungalow—indeed more or less all over the estate. Every superintendent in Ceylon, but especially in the lowcountry, should make a point of planting an abundance of fruit trees; and every proprietor should insist on this being done. There is no estate to which coolies can be got so easily, and in which they settle down so readily, as that on which they can obtain fruits either free or to purchase; while to Europeans plenty of vegetable diet means health in the lowcountry especially, and to have such a variety as we find in this estate means luxury too. The following list gives you some idea, and was just penned from memory:—Mangoes (varieties), mangosteen, roseapples (varieties), guavas (varieties), soursop, custard-apple, almonds (varieties), Brazilian cherry, lovilovi, bilimbi, oranges (8 varieties), limes, citrons, pomegranate, avocado pear, shaddock, grenadilla, jambu, tamarind, plantains, splendid pineapples, grape vine, and several others; while tomatoes, knolkohl, lettuce, cabbage, beans, radishes, spinach, onions, bandakai, &c., with a nice collection of crotons and flowers prettily laid out, complete the contents of a garden, as tasteful to the eye as the palate, and a preserver of health in itself.

But it is getting dark, and there is only time for a bath, before the lamps are lighted and we sit down to a most enjoyable meal, seasoned with a pleasant flow of stories from our host of "days of old," which make the time fly so fast, that we are astonished to find it so soon time to "turn in" when we would fain listen all night to such interesting "yarns."

After a very early tea next morning, I started off for Delgolla estate in Kurunegala.

The distance is twenty miles from Udapolla, but by the arrangement of our kind host of last night, in the shape of relays of bullocks at different points on the road, it was easily reached by 10 o'clock a.m.

The drive along this fine road is very pleasant in the cool of the morning, and the continual change of scenery makes it interesting too.

PADDY HARVESTING.

Harvest operations are in full swing amongst the villagers, and the "increase" in their case this year seems to be bountiful. Large numbers of small ricks or stacks were piled along the paddy-field bunds, while the uncut paddy seems to be hanging nearly flat in many fields with the weight of the grain.

ACCLIMATIZED TAMILS.

I was surprized to see such numbers of Tamils settled in the houses alongside of the road, and a planter made the remark in explanation of it, that when once a cooly gets acclimatized to the Kurunegala district, he rarely leaves it, which I could readily understand from the numbers I saw. Most of them were previously engaged on the abandoned estates round about, and their remaining on in the district is a great advantage to the estate superintendents, who, in their busy season, can get any extra coolies they require at once, and pay them off immediately the work is done.

DELGOLLA ESTATE.

At about 10 o'clock a.m. I reached Delgolla estate, and a short drive along a road lined on either side with rubber and fruit trees, and with neatly trimmed hedges, brought us to the bungalow.

This being the busy season, Mr. Fox did not arrive for some time and this gave me time to write a few letters, which I did.

In front of the bungalow a long avenue stretching away over a mile, and lined on either side with cocoa and jak trees, with a little hill in the distance crowned by a Buddhist temple produces a very pleasing effect.

When the trees grow up and shade the avenue, this will be a very pleasant promenade.

500 ACRES OF COCOA.

After breakfast we start for a round of this truly magnificent sheet of cocoa, Delgolla and Dynevor having between them an unbroken field of 500 acres.

SHADE FOR COCOA.

On both of those estates shade trees have been left all over but they are being gradually thinned out and replaced where necessary by valuable timber trees of quick growth such as jak, halmilla, &c.

After a couple of years cocoa requires much less shade than at first; indeed it can be planted without any, in sheltered places, but trees help to act as windbelts till it is firmly started, when by the arrangement of its own leaves the tree shades itself in an umbrella fashion, completely protecting the very delicate flowers from the rays of the sun.

ROOT GROWTH OF COCOA.

The most careful planters have observed that for about two years at first cocoa is mostly a taproot-feeder, and during this period may make very slow progress, but at about two years old it begins to throw out lateral roots freely and grows away with astonishing rapidity.

THE "SINE QUA NON" OF A SUCCESSFUL CLEARING.

Careful planting the first year and the absence of failures are the *sine qua non* in a successful clearing, which no amount of supplying will ever make up for.

All the planters here use baskets, pots, or transplanters, and in one clearing on Delgolla I saw, in 40 acres only 75 failures had occurred.

PLANTING AT STAKE AND IN POTS.

Here planting at stake has been very successful too but I think that this is accounted for partly by the white-ants not attacking the plants (a most curious circumstance, as there are white-ant hills all over the estate). Pots seem to be most commonly in vogue and are available for several seasons if carefully used, and, although the first cost is higher than baskets, they are as economical in the long run.

DISTANCE BETWEEN TREES.

The cocoa on Delgolla is planted at various distances from 9 ft. × 9 ft. to 13 ft. × 13 ft. apart: the former with a view of getting the ground covered and shaded quickly, and large maiden crops; and then by removing every other plant the remainder will be about exactly 13 ft. × 13 ft. (as 9 ft. x 9 ft.=82 ft. and 13 ft. × 13 ft.=169 ft.) which is the distance the planters here seem to think cocoa will ultimately cover. The trees in the field planted 9 ft. × 9 ft. are already met in the lines, and form a complete shade to the ground, on which the fallen leaves are beginning to make a layer of mould round the roots. Moisture and cool below and heat above are what cocoa delights in.

PRUNING—ESTIMATES OF CROP—COST OF OPENING ESTATE.

Mr. Fox goes in for pruning out all cross and dropping wood below, leaving fine strong upward growing primaries with strength to bear any amount of pods, and on many of them long rows of pods indicate the suitability of this treatment. On Udapolla I refrained from giving estimates or figures in regard to the cocoa, as it is so comparatively young but here we have figures to go by, which show what a profitable cultivation cocoa will now be in Kurunegala. On the trees in their 4th and 5th year there is a crop being gathered of 4 cwt. per acre; and the estimate will most likely be exceeded. This is selling at R50 to R55 ₱ cwt., and Mr. Fox's forecast for next year of 5 cwt. per acre from the same trees appears very moderate in view of the difference in age. The cultivation of a cocoa estate when once established is the simplest we have in the island, and the opening of an estate and bringing it into bearing need not cost more now (including cost of land) than R120 to R150 per acre. Suitable land is not very plentiful, at least land of the same description as Delgolla and Dynevor, which are nearly flat and fine soil. The only difficulty appears to be in the curing, in which the beans, as in the case of tea, must be fermented to a certain point, and then fermentation stopped at once; otherwise the sample is inferior and price lower. On every cocoa estate a "clerihew" and steam or water fan will be required to dry the cocoa, in the event of wet weather, and already these have been erected on

Delgolla, and have been doing useful work during the showery weather we have had lately.

CURING THE BEANS.

A cooly picks two bushels of cocoa beans per diem, and as 5 bushels wet = 1 cwt., the cost is only about 87c a cwt. for picking as compared with R2 to R3 for Liberian coffee. The pods are first cut from the tree, a small piece of stem being left on the tree, and the cooly takes one in each hand, and with a knock breaks them both in halves, and then with one draw of his fingers dexterously strips all the beans off the centre pulp. The pods are then thrown down round the trees and act as manure, while the beans are removed to the fermenting cisterns. It takes from 5 to 9 days to properly ferment the cocoa, and it is then ready for washing. It is trampled first, as in coffee with the feet, and then is removed in baskets and carefully handwashed, as washing with the "matapalagei" damages the beans.

I have no doubt that erelong some means less expensive will be found for washing, and the clerihew will be much improved on too.

After washing, the cocoa is laid on mats to dry as coffee is, if the weather is suitable; and at times it is advisable to give it a rub over with small pieces of sack or cloth, which improves the appearance of the beans, and facilitates drying in this showery weather.

The difference in well cured and badly cured cocoa amounts to at least R20 per cwt., and the prices obtained for it, as in tea, will depend in a much greater measure on the careful attention of the superintendent to the curing, than in the case of *Coffea Arabica*, and the good man will have a better chance of coming 'to the fore' than in days of old with coffee.

RIPENING OF CROP.

It seems strange that cocoa on young trees does not ripen nearly so quickly as on trees over 4 or 5 years old, but the crop season in cocoa as in Liberian coffee extends over eight months of the year—which is a much less severe strain on the trees than if it were confined to three months as in the case of *Coffea Arabica*. By the time we had got round the estate it was getting late, and I returned to the bungalow more than pleased with my visit to this grand sheet of cocoa, which I cannot say more for than that it has exceeded the most sanguine expectations of Mr. Fox, the part-proprietor and superintendent, and we all know what that means, and how sanguine we are over the paper calculations, in the case of a new venture—too often alas! to be disappointed.

SQUIRRELS.

Squirrels used to destroy a lot of cocoa pods by eating through the shell, when the beans go bad at once; but after employing a watchman with a gun to shoot them for two years they are practically exterminated now, on this estate. At first he used to kill six to eight a day, but now he gets two with difficulty; however he must have been the death of some thousands of those "festive little cusses" first and last, and I wondered that he had never preserved their skins, as the fur is pretty, and would sell well at home, doubtless. He would do well, even now at the eleventh hour of the squirrels' existence on Delgolla, so to speak, to take a leaf out of the book of his American contemporaries. These squirrel-hunters use bullets only, and shoot the branch the squirrel is sitting on, when by the shock he usually drops stunned to the ground, with his coat perfectly uninjured. When squirrels are scarce and skins in good demand, his coat is carefully removed something on the principle of cinchona stripping, when I was assured it renews perfectly from 6 to 9 months, and having a much larger percentage of soft hairs, which sell at so much a unit, the renewed skin is much more valuable than the first one.

FRUIT AND RUBBER TREES.

But to return to our subject of "New Products." Round Mr. Fox's bungalow are a large number of fruit and rubber trees, the latter the result of a very moderate investment in seeds and plants (I forget which), amounting to R2·76 (two rupees and seventy-six cents), and from those trees Mr. Fox has sold R1,500 (fifteen hundred) worth of plants and seeds—a very good return for his money!

There can be no doubt that a few rupees invested in many of the new products now being advertized would, as a rule, pay handsomely, while, should the extension prove likely to be successful a nucleus having been formed, it would be an easy matter and inexpensive to extend the cultivation at any time.

After dinner, to which a neighbour came in, weary with his long round of work in this exhausting climate, the bullock driver got instructions to "hitch the insect," and I was soon rattling back merrily to Udapolla, which was reached somewhere about the wee short hour ayont the twal', and my conversation with Mr. Jardine (so far as I can remember) amounted to:—"You 've got back all right?" "Yes, thanks." "You look very sleepy." "Yes, good night!" I scarcely remember even this much.

LIBERIA ESTATE:—THE COFFEE CROP.

Liberia estate lies about four miles from Udapolla, part of this being along the edge of the railway, and after leaving Udapolla about 8 a. m. I reached Liberia in time for a walk before breakfast. The trees here are in good heart. Leaf-disease has almost entirely disappeared. A fine blossom just out augurs well for next year's crop, which Mr Sturgeon expects to amount to 2,500 bushels parchment. The coffee on this estate is very widely planted 10½ ft. × 10½ ft. on an average, but cocoa, which is coming on remarkably well, is being planted all over the estate with a view to supersede the coffee later on. On this estate there is about 100 acres coffee planted and in bearing, and the present crop, 2,000 bushels, is at the rate of 4 cwt. per acre at this wide distance, and with a good many vacancies, or planted 7 ft. × 7 ft. at the rate of 9 cwt. per acre!!

As in the case of Delgolla and Udapolla the estimate this year will be fully got if not exceeded, and the cocoa is already beginning to bear in some of the first planted fields; 50 cwt. of a crop will be got from it next year, a few cwt. being already in store. This will increase very much for the next few years till all comes into bearing.

The country all round here (except on some ridges) seems best suited for cocoa, and the protection afforded by the coffee to the young plants helps the cocoa so well, that in a short time we may expect to find all the estates on this side—cocoa estates, with coffee as a subsidiary product—in fact every estate round about is being fully planted with cocoa so far as I could make out, and the several clearings being filled this year are all for cocoa also.

One enterprizing proprietor is this year planting up a clearing between the lines of coffee with tea, and with such an ample and well, distributed rainfall as there is, (which I was astonished to see, and annex), there seems every reason to believe it will succeed well. The average is about 105 inches for the two years, and it rained in every month, February being the driest, and October the wettest month of the year:—

TEA.

In a year or two hence, tea will have had a fair trial, and we will then be able to speak of it as we can of the other products now—from experience. Several of the estates in this district near the cart road manure the coffee and cocoa with manure, collected from the cart-road cattle sheds, at which there is a lot available.

MANURE.

Mr. Jardine carts manure from Kurunegala, a distance of 9 miles, and lands it on the estate at about R6 per acre, allowing a bushel per tree, or 75 cents per cart, including purchase money (about 12½ cents per cart).

RAILWAY TRANSPORT CHARGES.

Mr. Sturgeon on Liberia was desirous of taking advantage of the railway to transport manure to the estate (Liberia), having to cart, and the railway passing along the boundary. The late careful Traffic Manager only asked the very moderate sum of R4·40 per ton for 2½ miles transport!!! Mr. Sturgeon requiring to load or unload the manure. Calculating that Mr. Jardine's carts only take ½ a ton, it only costs him 16 cents per mile per ton landed on any point of the estate, compared with about R2 per mile here, with the additional expense of loading and unloading. Of course this stopped the work being carried out, but it is surely very hard to think that instead of giving every possible assistance and encouragement to new product planters Government officials seem, in many cases, to put as many difficulties as possible in the way.

THEFTS OF PRODUCE.

Another case came under my notice is this district, of a man who was caught stealing in the act, with a bag of cocoa pods ready to be removed; he was fined R10: a friend who had also a bag picked ready for removal escaped free. Now the magistrate who tried them, a Sinhalese gentleman, must look on robbery of this kind from a very lenient point of view, and a little reflection on his part would at once convince him of the amount of damage he has already done; as a man can remove in one load R20 worth of cocoa beans, and it is almost impossible to catch the thieves in a large cocoa estate therefore it strikes one most forcibly, seeing that the chances are about 50 to 1 against the thief being caught, he is likely to make a fairly good thing of it, in the course of a year: in fact by this singular punishment on the part of the Galagedara magistrate, he has fairly laid the foundation of a new industry for his fellow-countrymen, doubtless unintentionally, and let us hope that the next offender may get punishment in lashes and hard-labour somewhat adequate to his offence.

A FINE RUBBER TREE.

One india rubber tree in front of Liberia bungalow 3 years old measured 2 feet in circumference 18 inches from the ground, and is very high and the milk very thick.

THE CARBOLIC ACID CURE FOR LEAF-DISEASE.

I saw the area treated on Udapolla with carbolic acid, and quite agree with what Mr. Jardine wrote to your paper lately: and in one case I felt the carbolic acid fume, strongly, several feet from the tree, which had leaf-disease on it, and a tin of pure carbolic beneath it!

CHEERING PROSPECTS FOR OLD AS WELL A NEW PRODUCTS.

When the foregoing notes were written for your journal, I had not seen your junior editor's very able papers on "Matale revisited," which every one must have felt extremely interested in, and I now send on the balance of my notes feeling sure that at the present crisis, as a sequel (however poor) to those letters just referred to, they will reach you at an opportune moment, when their appearance can do no harm, but may possibly do good by cheering some hard-worked planter on the verge of despair, and I feel certain that anyone who takes a trip over the ground I have just gone, and sees what I have feebly described, will exclaim like the queen of Sheba that "the half has not been told," and in the not very far distant future there is a likelihood of comparative prosperity to the country again, when we shall be able to look on days of depression as a thing of the past, and instead of only one great staple the failure of which, in a bad season, brings such disastrous effects, we shall have a variety of products, and be more or less independent of the failure of any one of them any year. The year that may be disastrous for one crop (as the late one for coffee) is exactly suited for another (as last year was for tea), and the happy planter will then be able to console himself with the reflection, that "it is an ill-wind that blows nobody any good," and that "his eggs are not all in one basket."

If in the figures I have quoted there are any errors, I apologize to the gentlemen who so kindly gave me the information; but one conclusion only can be arrived at from the foregoing, which is, that in the 1,500 acres of cocoa, besides Liberian coffee, rubber, &c., which are flourishing on Liberia, Udapolla, Delgolla, Dynevor, Lowlands, Cairnhill, Lismore, Rockeave, and a number of other equally good estates in this vicinity, the nucleus of a grand district has been formed, which in a few years will have thousands of acres under "new products"; when the present pioneers will have the satisfaction of seeing what benefactors they have been to the country, and also of knowing that in their early investments they made a really "good thing" of it, a very unusual circumstance in this world with pioneers.

"Then happy lowly* heads lie down,
"Uneasy lies the head that wears the crown†."

ALKALOIDS IN *C. SUCCIRUBRA* AT HIGH AND LOW ALTITUDES.

All connected with the culture of cinchona will read with special interest Dr. Trimen's letter given on page 864. From this it will be seen that a difference of altitude of 4,000 feet in favour of a tree over nineteen years old grown at Hakgala over one of equal age grown at Peradeniya, resulted not only in more robust growth and more than 3½ times more bark, but in a proportion of alkaloids, especially of the more valuable kinds, enormously greater. Unless, which is not very probable the tree at Hakgala was specially sheltered from wind, the case in favour of high altitude is exceedingly strong. If those who own high estates could only trench the ground to 4 feet or so, they could no doubt grow the vigorous *C. succirubra* to great profit. Now that shaving has been adopted, of course there would be no necessity to wait more than a fourth of the period of the growth of the trees experimented on.

THE PLANTING ENTERPRISE, ACTUAL AND PROSPECTIVE, IN TROPICAL QUEENSLAND AND THE "NORTHERN TERRITORY" OF SOUTH AUSTRALIA.

To a correspondent, who is turning to good account, in Northern Queensland, planting experience obtained in Southern India, we are indebted for the following very interesting details:—

The state of the planting industry in Queensland at present is fairly prosperous. Mackay, hitherto the premier sugar district, will, perhaps, have, comparatively speaking, the worst outturn. At Bundaberg a large area—heretofore a cattle station—has been bought by a syndicate who are now advertising for sale and lease in sections of 20 acres and upwards, and promising to put up a central mill to crush the cane. They have founded the township of Barolin and are claiming for it points over which Ruskin and Dr. Richardson would agree. The Pandora Sugar Co. has satisfied the people of Rockhampton that their neighbourhood is suitable for sugar. Proprietors of the rich scrub lands in the Logan valley are also offering land for sale or lease in small acreages, undertaking to give 10s per ton for matured cane as it stands in the field. This plan the Colonial Sugar Co. has largely adopted in New South Wales and Fiji, and it is found to answer well for all parties concerned. Many people who do not care notwithstanding liberal terms to take up land on the outposts of settlement readily avail themselves of this arrangement by which they are sure of a fixed return for capital invested. On the Burdekin Delta £250,000 has already been expended on the plantations. Andmillan

* Lowcountry.
† Of King *Coffea Arabica*.

is to be extended to 5,000 acres. This district, like Mackay, Barolin and the Herbert, is what colonials term "open bush." The soil is of considerable fertility, but commend me the jungle or "scrub" as it is called here. Hundreds of Chinamen, as on the Herbert, Johnson and Cairns, are employed. The Kanakas employed on the Burdekin are an insubordinate lot, and I fancy turn out in the end very expensive labour, one nearly cut off an overseer's hand a short time ago, and it was the mutilation of that member that saved his head. It is observable that the contact with European labourers makes them worse workmen. They are made too much of by ploughmen and others; and the Kanaka overseer, who thinks he is bound to keep his nose at a certain angle, has often the finger of scorn pointed at him by the white workmen and generally in the presence of Kanakas. As may be expected, however imposing the overseer may be, he does not carry much moral or other influence under such circumstances. I have had very good accounts of the conduct of these Islanders on the Johnston and in the Cairns district, and so no ploughmen, owing to its being scrub land, are employed there, the milk in the coconut is accounted for. I had to do with the working of a large mob of Kanakas for a twelvemonth, where no white men, save overseers, were employed, and more reliable and satisfactory labour could not be found anywhere.

The pioneers of sugar planting are to be found on nearly every river of consideration so far up as the MacIver near the extremity of Cape York Peninsula. I am sure there has already appeared in your columns an extract of the Rev. J. Tenison Wood's graphic account of rich jungles between Cardwell and Cape Hattery, a distance of some 120 miles. I have been enquiring of people who have been to Normanton and the country bordering on the Gulf of Carpentaria, and no one seemed to consider it suitable for planting enterprize. The inspection of practical men may yet modify this opinion.

I had a long talk with a person down from the Northern Territory of South Australia. He says the white-ants are likely to have a disastrous effect on the sugar industry. They devour the roots of the cane. It is the only agricultural venture there yet, but he spoke of a Company that had been formed somewhere for a coffee plantation—probably the gentlemen from Ceylon who took up land sometime ago, as reported in your columns. There is very little jungle, and also no ranges of consequence, but the open forest is of more than ordinary fertility and the rainfall perhaps larger than anywhere in Australia.

Mining also is a poor speculation there, and not to be at all compared to the flourishing condition it has attained in Victoria and Northern Queensland. The whites have to abandon their alluvial claims to Chinese, who appear to stick to them so long as they can get sufficient to buy "the smell of an oil rag," which is reckoned hereabouts their hard times fare.

Northern territory is unhealthy: my informant being a specimen of the enervating effects of bad climate and fever *pucka* jungle-fever.

Coolies have not yet landed there: at any rate they had not before he left.

The price of land has been raised from 7s 6d to 12s an acre, and the advance has caused great dissatisfaction that has found vent in the columns of the Sydney newspapers.

The land surrounding the ports of Palmerston and Port Darwin, he told me, was owned by English capitalists. They no doubt look forward to handsome returns when the transcontinental railway becomes a matter of fact.

With labour at reasonable rates coffee planting will become one of the great industries of Queensland. Even now it should prove remunerative, for when one can get 160 acres for 2s 6d an acre, the payment of this moderate sum spread over five years, he can afford to give a fair wage. The settler of small capital could not embark in a better undertaking, for, different to the sugar farmer, he would be independent of any possible caprices of a mill owner, and a young family would be quite equal to the large amount of light work fortunately attached to this cultivation. As to the question of the plant being at home here, there can be no doubt: I myself have seen on trees in the Brisbane Botanic Garden as good a crop as I have ever beheld on the slopes of Travancore or in the Pacific Islands, and I have heard especially good accounts of the Millicent Plantation Mackay, and Gairloch estate in the Herbert River. I also saw with pleasure some young plants at Spillers in the Lower Burdekin, that looked strong and healthy, proving it is not too fastidious to content itself with good open forest soil. At Gladstone near Rockampton, many have got small gardens of the berry, and even so far south as the Logan Valley, which by the way is in N. S. W., the plant makes itself thoroughly at home. An old bushman, native of the colony, told me there were interminable forests of heavy scrub on the mountain sides between the Richmond and the river above named. If they can be utilized for coffee what a paradise for the planter! Soil and climate equal to any in the world, and white labour at half what it costs in Northern Queensland. I saw a few full-grown plants in the Botanic Gardens, Sydney, and even in that climate they had a few berries on their sheltered sides, which, however, as might be expected, were dwarfed and ill-formed.

From the Herbert in the south, far to the north, and for hundreds of miles to the west of the coast ranger a *terra incognita* lies, which, so far as it has been penetrated, shows a dense jungle, with soil of the greatest fertility and an abundant supply of water. It should also suit coffee together with other products. The name of "the Garden of Queensland" is already being applied to this region.

I had the pleasure of making the acquaintance of an enthusiastic bushman and daring explorer, Mr. Christopher Palmerston of Cairns, and when I touched upon the topic of coffee he gave it to his opinion that the Daintree river was the most suitable place for its cultivation he had viewed in all his wanderings.

The Anti-Coolie League is an established institution. From Townsville a delegate has been sent farther north to harangue and agitate. Considering the emigration not that has been passed in your colony, and the similar one that exists in India, the league is now really "fighting the air." It answers well as a political "bogie" however, the party fighting for the Anti-Coolie principle are pretty certain to get into the power soon. "Queensland for the white man" is the sentiment of nearly every workman in this colony, and no one can be here long without in some degree sharing it. The expediency of colonizing tropical Australia with Europeans is however open to question. The rising generation certainly exhibits a falling back in at least the physical attributes of his forbears. Whether this is merely an adaptation to climatic conditions, or the beginning of a series of stage of degeneracy can be settled only I imagine by time. Would it not be the wiser policy for the Imperial Government to direct the stream of emigration in the future to those temperate climes and fertile countries, which Britain possesses in such profusion until the suitability of Queensland for the Anglo-Saxon and Celtic race is beyond question. Let us hope however that our race is suited to people this beautiful country and that the inhabitants of Queensland will reach Charles Kingsley's beautiful ideal of a tropical people.

CEARA RUBBER.

TO THE EDITOR OF THE "PLANTERS' GAZETTE."

28th February 1883.

SIR,—I hear from Mr. George Wall today that he has made a round of several plantations growing the Ceara rubber trees in Ceylon, and he has tapped a great many of the stems of the Manihot Glaziovii on different plantations. From some trees he gets the richest rubber, which comes out so thick it is nearly solid, in a short time; from other trees only a watery discharge, which is almost valueless.

This is an extremely important fact for merchants on this side to be made acquainted with, and it thoroughly confirms my previous letters stating that the authorities in Ceylon should instruct their assistants to carefully watch the trees that yield valuable products, so that they may be enable to decide at what time of year the trees ought to be tapped, and also to ascertain if there is any difference in the trees. It is also important to know if the soil has any effect upon the quality of the indiarubber.

We can do nothing on this side, but surely Dr. Hy. Trimen, of the botanical gardens, Peradeniya, could investigate this subject, and I am much indebted to Mr. Wall for this valuable information.—Yours truly, THOS. CHRISTY.

Correspondence.

To the Editor of the "Ceylon Observer."

MR. GAMMIE ON THE COST OF CINCHONA FEBRIFUGE IN NORTHERN INDIA.

Darjeeling, 15th March 1883.

DEAR SIR,—The statement in your overland issue of the 24th February, which reads as if made on the authority of the Milan quinine manufacturers now travelling in the East, that "the febrifuge prepared in North India at a cost of from 20 to 25 rupees per lb. could be supplied from Europe we are told for R5 per lb., with a large profit," is as manifestly absurd as scarcely to require contradiction. Were it correct the prospect of cinchona planters, more especially of the growers of *C. succirubra*, would be gloomy indeed. Analyses shew that even with an exhaustive process of manufacture, which means an expensive process, as may be seen from the charges of the London manufacturers, printed in your columns, for manufacturing the Madras Government bark, the average yield of *C. succirubra* bark, *i. e.* of the mixed root, stem and branch barks, is not more than 5 per cent of total alkaloids: hence 20 lb. of bark are required to make 1 lb. of febrifuge. In other words, to admit of the febrifuge being sold at R5 per lb., planters would have to grow, pack, ship and sell their *C. succirubra* bark in Europe at about fivepence a pound *minus manufacturing charges and the "large profit."* This would be equivalent to the unfortunate grower making a present of his bark to the lucky manufacturer and giving him a trifle besides for so good-naturedly taking it off his hands,—a prospect, however pleasant from the manufacturer's point of view, barely encouraging to the planter. But as a proof that this *happy* state of affairs has not yet been reached, I may mention that Mr. Böhringer of the Milan quinine factory told me that if the Bengal Government would sell their febrifuge at a price he named, and which is considerably higher than double R5 per pound, it would pay his firm to buy it all up and manufacture it into the different sulphates, &c. Readers of your paper will know from the annual cinchona reports that the cost of preparing the febrifuge in North India is less than half the figure quoted by your informant. Possibly a drug *similar in appearance* to the North Indian febrifuge can be procured from Europe at R5 per lb. but it will be of a *very different composition*. JAMES A. GAMMIE.

[Mr. Böhringer was our authority, and spoke of the matter as if he had discussed it fully, in the sense we gave, with Mr. Gammie. To any less authority we should not have paid any attention in making so extraordinary a statement; for clearly Mr. Gammie is right in showing the absurdity of the figures.—ED.

THE SOLA PITH PLANT OF INDIA.

Brisbane, 20th Jan. 1883.

SIR,—Efforts are being made to establish on the margins of our lagoons the sola pith plant of India and Ceylon. It would doubtless grow to perfection in Queensland and provide without the labor and cost of cultivation a large amount of raw material useful for many purposes which would contribute to comfort and health.

I should be grateful to any of your readers who would take the trouble to give in your columns a few plain directions, as to the best mode of establishing the plant, its habit of growth, time and method of harvesting and subsequent treatment.

Anyone also who would send a small quantity of new seed might rely upon a return in kind or otherwise if desired.

I should add that the plant was once introduced into Queensland through the instrumentality of Baron von Mueller, but its habits were not understood, and it has quite died out.—Yours obediently,

INDUSTRIAL BOTANY.

[The shola or sola pith plant of India is so called from the Hindustani name of the plant. This is the *Æschynomene aspera*, Linn. and grows in Ceylon in rice fields, and all flooded places amongst grass and other plants. The portions of the stems of this plant growing under water are covered with a thick white spongy excrescence, evidently intended to protect the plant in some way, and this is what has most erroneously been called the "pith" by several writers, and even repeated by Baker in the *Flora of British India*, I. 152, so lately as 1876. Dr. Roxburgh's short account of this plant—viz., "Common on the borders of lakes of sweet water in most parts of India. Flowering time the rainy and cool seasons. The larger plants are particularly light, white and spongy; they are gathered during the dry months of April and May, and converted by the natives of Bengal into a great variety of toys, floats for fishing nets, gentlemen's hats, &c."—conveys a correct idea of the plant and its uses. I have no doubt the plant will grow in favorable localities in Brisbane, but much doubt the realization of the hopes expressed by your correspondent of its profitable growth in Queensland in competition with Bengal and its cheap and abundant labor and vast tracts of country in which the plant naturally grows. The *Æschynomene Indica* is now in abundant fruit in Colombo, but I have not secured seed of the sola plant at present: as soon as I do so I shall send you a good supply for your correspondent. The seeds should be sown in mud, and then put out into the shallow edges of the waters which are supposed to suit them. I regret that I have no correct account of the mode of manufacturing the white excrescence called sola to refer to. For an exhaustive account of this plant, I refer you to that by Mr. R. Morris in an issue of the *Ceylon Observer* some time ago which is well worth a re-issue in your *Tropical Agriculturists*. For an explanation of the terms "pith" and "bark" see Bentham's *Outlines of Elementary Botany*, paragraph 198, and sections 1 and 5 of the same para. The pith is in the centre and the bark on the outside of an exogenous plant.—W. F.]

TEA PLANTING IN CEYLON: MASKELIYA DISTRICT FOR TEA.

26th March 1883.

DEAR SIR,—I promised to let you know what I thought of this district for tea, and my opinion is that, had it been planted with tea instead of coffee, it would now have been the most valuable plantation district in Ceylon. I was simply astonished to see the growth of tea in this valley.

On Eltindale, and on what most men would think rather poor soil, the growth was perfection for the age of the plants.

I think there is yet a great future for the Maskeliya planters, and I can name a few estates at least that will grow that "awful" 700 lb. per acre when in full bearing.

Ovoca, the property of Mrs. Gray, will just "walk down tea street." Bunyan and the level lands of Adam's Peak estate and about half Laxapane will grow very fine tea; but the picture place of the whole district, if planted up with tea, will be Bitterne estate. I saw the finest growth of tea for age on this estate that I have seen in Ceylon. There is seed now in nurseries to plant up the whole estate and I wish the proprietors the success which must naturally be expected on such soil. There is no doubt that the best tea planters have a great deal to learn about tea, and, as I have often remarked, our superintendents should visit each other, exchange samples and ideas, and all proprietors ought to give superintendents at least fifteen days' leave a year to go round and visit other estates. If they can see nothing to copy, it is possible that they will see something to avoid.

Perfection in tea manufacture will never be acquired by sticking all the time on *one estate*, and, as tea planting is a new thing here, let us all help each other and let none of us think that we know too much. I have seen lads that had only been at tea-planting a few months, strike out new ideas and teach men that had been at work for 20 years on certain points of tea manufacture. Now I know a little about tea myself, having gone through all the branches of the department, but on rounds I often see plenty to learn from men who have only started tea-planting. For instance the other day while in Maskeliya I saw a very simple dodge for sifting, which in future should be called "Tom Gray's patent." It was simply three sieves placed above each other slung by two wires and worked by one boy, doing as much work as three men could have done. This saved two-thirds of the labor usually required for this work. Now such hints as this are well worth noting, and the inventor deserves the thanks of all tea planters, for although simple in itself the plan is most effectual. —Yours, CHA.

THE EFFECT OF ALTITUDE ON THE ALKALOIDS OF RED BARK.

Peradeniya, 5th April 1883.

SIR,—Everything that may throw any light upon the relationships of the cinchona-alkaloids, or on the causes which influence their production, is of much interest; it also has a practical value to cultivators. I therefore no longer delay in making public the results of two remarkable analyses of Ceylon *C. succirubra*.

With the object of ascertaining the effects of altitude on the alkaloid-production of this species, I, towards the end of last year, barked two trees growing respectively at elevations of 5,500 (Hakgala) and 1,500 (Peradeniya), a difference of 4,000 ft. The trees were, I have every reason to believe, of common origin: both being, in all probability, raised from the original seed collected in South America by Dr. Spruce, and planted out in the midst of other trees, in or about 1863. They were therefore about 19 years old reckoned from the planting, and both had grown up under fairly similar conditions excepting as regards climate. Their growth, however, had been very different. The tree at Hakgala was one of the largest there, 37 ft. high to the point where the stem was but one inch in diameter and 37 inches in girth at the base lessening to 24 inches at 5 ft. from the ground. It afforded 25 lb. of dry bark (77 lb. of wet), and the sample sent home was large quill 18 inches long with a "brown coat." On the other hand, the Peradeniya tree though not far off the other in height, being drawn up by the large trees around, girthed only about 20 inches near the ground and yielded about 7 lb. of dry bark (21 of wet). The sample of small quill sent home was described as having a "gray coat."

It is to my friend Mr. J. E. Howard, who is ever most liberal in helping to advance our knowledge of quinology, that I am indebted for the following comparative analysis of these two samples. He is himself much interested in the result, and we may, I believe, expect some observations upon it from his pen:—

	Quinine Sulphate.	Quinine.	Cinchonidine.	Cinchonine	Quinidine.	Amorphous.	Total Alkaloids.
A. Large quill grown at Hakgala 5,500 ft.	2·75	2·06	3·47	0·61	Trace	0·66	6·80
B. Small quill grown at Peradeniya, 1,500 ft.	0·62	0·47	0·05	1·67	0·30	1·06	3·55

A comparison of these very different analyses suggests many observations. And at first sight we cannot but be struck with the influence for good of elevation in the production of the alkaloids as a whole, nearly double as much being produced in the higher locality. Mr. Howard remarks that as far as the *appearance* of the bark is concerned the contrary was the case, that from the low elevation being the "more attractive to those who judge merely by the eye."

The large amount of quinine in analysis A is also noteworthy in red bark from a tree nearly 20 years old, as showing that there is no necessary diminution of that alkaloid after 8 or 9 years, as Mr. Broughton was led to believe.

It is however as regards the proportions of the alkaloids that the comparison will be found most instructive. In A we have of quinine over 2 per cent, and of cinchonidine nearly 3½ per cent, whilst there is but 0·61 of cinchonine and a mere trace of quinidine: in B the change is very remarkable: quinine has sunk to less than ½ per cent and cinchonidine to little more than a trace (0·05 per cent), whilst on the other hand cinchonine has increased to 1·67 per cent—that is, about 2½ times as much as in A—and there is also an appreciable amount (0·30 per cent) of quinidine. It has been remarked* that the natural or physiological relationship of the four principal alkaloids of cinchona bark is not expressed by their chemical constitution and terminology. Quinine and quinidine are, as is well-known, isomeric chemical bodies, *i. e.*, both have the same empiric formula of composition, C_{20} H_{24} N_2 O, and cinchonine and cinchonidine are similarly related, their common formula being C_{20} H_{24} N_2O. But in nature it would appear that the pairs are differently composed, and it is customary to find associated in the tissues of quinine and cinchonidine and cinchonine and quinidine and not the isomeric couples. It is indeed highly probable that, under conditions of oxidation and deoxidation at present not understood, the units in each of these naturally associated pairs are mutually convertible. The analyses before us bring out this association in a very marked manner.

The relationship of the alkaloids to which attention is here called is also indicated by the action of their solutions on a ray of polarized light. Quinine and cinchonidine deflect this to the left and are lævo-rotatory, whilst cinchonine and quinidine have a right hand or dextro-rotatory action.

As to the causes which in the case before us have led to the disappearance of the quinine and cinchonidine in the low-grown bark, and their partial substitution by cinchonine and quinidine we have little to guide us, but the fact is a very important one as bearing on the cultivation of red bark at low elevations. A similar substitution has been recorded before in old trees, but age alone is seen by analysis A to be an insufficient cause. It is probable that temperature is the more important factor, and support is given to this by the remarkable case recorded by Broughton† of the reversed action in *C. peruviana*. This species as grown at Neddivuttum is remarkable for affording cinchonine in large quantity —in the experiment recorded 3·84 per cent—and absolutely no quinine; when grown however at the higher elevation of Dodabetta, the cinchonine was greatly diminished, whilst quinine was present to the amount of 0·79 per cent.—I am, sir, yours faithfully,

HENRY TRIMEN.

WEEDING AND PRUNING OVERDONE?

DEAR SIR,—In my last I told you of an estate which had increased its crops through getting weedy. Now I could tell you of many estates that gave reduced crops

* Mr. Howard especially called attention to this so long ago as 1866 (see Proc. Bot. Congress in London, p. 198).

† Report to Government of Madras, 26th September 1871.

through being cleaned, but I will satisfy myself with the Nanuoya estate, the estate that was the cause of Dimbula being opened. When that was a weedy estate I believe it used to give 14 cwt. an acre. Has it done so since it has been made a clean estate? If it did, I do not think it would be kept dark. A writer in one of the papers has likened weeds to a standing army. So they are: they are King Coffee's standing army, and like all others must be kept down and in order, but not done away with. In a battle there are always two armies: one for and the other against; the weeds fight the elements and protect the coffee. Coffee being a surface feeder any intermediate crop for the benefit of the coffee must also be a surface feeder. We have been told what the white weed is and we have been told to grow an intermediate crop, so that what better or cheaper can we grow than the food for the coffee? In the weedy days coffee used to give its 6, 8, 10, and 15 cwt. an acre. Surely that ought to satisfy anyone. There is nothing that cannot be overdone and there is no doubt that weeding and pruning have been overdone. A tree can be weakened by over-pruning quite as much as it can by over bearing and does not land kept bare become barer or barren?—Yours truly,

G. F. HALLILEY.

HEMILEIA IS ONLY MILDEW AND SUCCULENT WEEDS AVERT MILDEW (?).

DEAR SIR,—It is now beyond a doubt that the so called leaf-disease is nothing but mildew. By a book kindly lent me by Mr. S. Green, entitled "Fungi, Their Nature, Influence and Uses," among the numerous varieties of mildew is mentioned *Hemileia vastatrix*, and from that book it appears that everything, tree, plant or herb, has its especial variety of mildew, or, as I said before, it adapts itself in a different form to the locality. Mr. Marshall Ward, I think, told us that he could find no germ of the disease in the sap of the tree. Now if he had found it in the upward sap it would have been proof positive that the mildew was in the soil, and the cure would have been ventilation of the soil and lime. Had he found any trace of it in the downward sap, Dr. Thwaites' prediction would have come true and coffee would now have been a thing of the past.* Mildew must have attacked the fruits of the earth in the time of Solomon. (See II. Chronicles vi. chap. and 28th v.) We know in fresh water there is no trace of mildew, and we know that anything damp under certain conditions gets attacked with mildew. If a tree takes up too much moisture without a sufficient supply of essential food, as soon as the weather changes to bright, hot sunshine the sap becomes disorganized and the result is mildew, so in this case there are two things required to prevent mildew, and they are a sufficient supply of essential food† and something to absorb the superabundance of moisture. A tree also gets mildewed from not being able to take up a sufficient supply of food for want of moisture, so that the more succulent the weeds are kept the longer they will supply the coffee with moisture in dry weather. In ornamental gardens it is very well to keep them clear of weeds: these gardens are meant to please the eye and are constantly being manured and in dry weather are watered night and morning. Now we have every proof that leaf-disease is nothing but mildew,* or how are we to account for its disappearing and at times suddenly appearing almost in a night all over a district and at other times only bursting out in a small patches few and far between? I have never seen it spread from these patches, unless there was a sudden burst of wet weather and then hot sunshine, when it was undoubtedly a fresh attack, so that the real and true cause of leaf-disease and all that ails our coffee is want of means to cultivate and being obliged to follow the fashion.—I remain, your truly,

G. F. HALLILEY.

[On which we have to remark that never since coffee was created was it better or more liberally cultivated than at the period when this deadly blight burst out to ruin the most luxuriant as well as the most exhausted estates. One of the main remedies proposed for the evil was the removal of those weeds for which Mr. Halliley so enthusiastically pleads. Not only do they rob the coffee trees of their "essential food," but they form a nidus for the spores of the fungus or mildew.—ED.]

MILDEW AND WEEDS, ONCE MORE.

DEAR SIR,—Mildew, though so minute a gathering, is still the great agent to convert everything after death to its original dust or ashes: as soon as a thing gets sick or weakened, mildew sets in ready to carry out its work, so that mildew is a natural consequence. In man when he gets sick it appears most commonly as fur on the tongue, but, as soon as he recovers, it disappears; so it is with plants and trees: as soon as they get sick or weakened, mildew appears, † when they recover it disappears, but, if the tree gets worse, the mildew follows up. Now, ask some of your readers that are near some shuck and abandoned coffee, to see if they cannot find you some branches that have a yellowish look about them, and see if it is not the same mildew following in the wake of death. When a tree takes up too much moisture, does it not get sick? Regarding your footnote, may I ask what good can manure do without moisture? If you put a plant into a pot of rich soil, that plant will die, unless it gets moisture. How can weeds rob the coffee if they are returned to the soil, and, are you certain that they derive all their constitutional [*sic*] parts from the soil? Now, suppose you fill a box with good soil, in one-half you plant a few cabbage seed, and in the other a few seed of the deadly nightshade, when those seed grow into plants, you would eat the cabbages without fear. Would you eat the deadly nightshade as readily? From whence do the deadly nightshade derive their poison? Not from the soil, or the cabbages would have been poisonous, and, if the weeds contain the same elements as the coffee, why should they not be attacked with the very same mildew as the coffee? You do not believe in shading the soil ‡: may I ask what mulching is but shading the soil?

Now, I will show you my experience of moisture in the soil. When I was S. D. on Barra estate, when pruning came on, I asked my P. D. if I might stump some coffee trees that had lost all but one primary at the top, and he told me not to talk of stumping, or I would get the sack. I asked why; and he pointed to a piece on the top of the estate, and said it was eleven acres, it had been stumped, a bedding of jungle stuff laid on the soil and over that a dressing of earth, and not one of the stumps

* Will Mr. Halliley read up and let us know whether there is a single well-atthenticated case of the germs of mildew being found in either the ascending or descending sap of a plant?—ED.

† As a matter of fact, duly recorded by Marshall Ward, a supply of "essential food" to the plant has been found merely to feed a larger and more luxuriant crop than ever of the fungus.—ED.

* No one, to our knowledge, ever denied that it belonged to the great family of mildew, smut, blight, rust, fungus. —ED.

† *Hemileia vastatrix* impartially attacks the healthiest as well as the sickliest trees.—ED.

‡ We certainly believe in shading the soil, but with coffee, not with weeds.—ED.

threw up a good sucker; a few days after, I went up to have a look at it, when I found that the earth had been taken out of trenches that might have done for a double-cutting for a small railway, and there was no doubt that these trenches drained the sap out of the soil, and Rakwana was at that time a wet district. When I threw up Palamcotta and went up to Hattarabage what was my astonishment to find, that every tree on the then estate had been stumped and every stump had thrown up a sucker and formed a good tree, and Hattarabage was a very dry place.—Yours truly, G. F. HALLILEY.

[We believe in too much moisture being bad and too little being equally bad, equally with our correspondent; but in the benefit of weeds we do not and are not likely to believe.—ED.]

COFFEE-LEAF FUNGUS—CARBOLIC ACID—AND CROPS—THE TRUE REMEDY FOR PLANTERS' TROUBLES.

"Gold'ne Früchte seh' ich glühen,
Winkend zwischen dunkelm Laub;
Und die Blumen, die dort blühen,
Werden keines Winter's Raub."

DEAR SIR,—I have read with much interest the letters which have appeared in your columns by "W." and others on coffee-leaf disease and its treatment by carbolic acid. In my own small way I have also tested the truth of the statements made by "W.," and I have found that a saturated solution of water contained 4 per cent of carbolic acid. "W." doubts, however, whether the acid is volatile. If not volatile it cannot come into contact with the fungus, and is useless. This is "W."'s surmise. Whether *volatile* is the correct term to use I doubt very much. I have tested the air in the immediate neighbourhood of trees surrounded by tins of acid, and I have found that the air contained carbolic acid. I cannot say in what state it exists, whether in the form of vapour, or very small particles. We know that salt exists in the air in the form of very fine dust in the neighbourhood of salt lagoons, &c., and I am inclined to believe that the acid must exist in the same state. Finer appliances than I possess would settle this point, and some of your Colombo chemists might inform us on the point.

I have not been able to observe that any good has resulted from the exposing of the trees to this acid. I think the experience of those who have used it will corroborate my views. As a cure for leaf-disease, carbolic acid is valueless. Are we then to look helplessly on the ravages of the *Hemileia vastatrix*, convinced that no cure is available? I think we must. The wise planter cultivates his coffee carefully, sees that his wood is in order: in fact, that his estate is in perfect order, should the blossom and the favourable weather come. He knows that this is all that is in his power. "God alone giveth the increase." He repudiates these miserable tins of acid: the cheeseparing which saves a few cents to his proprietor, but leaves his trees unpruned, his house unswept for the coming guest, and when that guest comes in the shape of good blossom, with fine favourable weather to set it, he is unprepared to receive him, and the opportunity is lost. The cheeseparing has cost the proprietor thousands. I appeal to the planters in general, if this is not the case with very many. Just now there is a finer prospect of crop than we have had for several years. The guest has come unexpectedly, and those whose houses are prepared to receive him benefit to the full, but those whose wood is not in order, to whom cheeseparing seemed the acme of good management, lose the golden opportunity. They cannot but benefit by the golden shower, but they do not benefit to the extent the careful husbandman does. Favouring seasons alone can mitigate, if not cure, this curse which has ruined so many fine estates. Artificial remedies are sought in vain. The fungus is the result of laws which we know to be invariable; natural laws the workings of which we can but weakly investigate. The fungus will disappear as it has appeared under the influence of these laws. Days of humiliation and fasting have been proposed as a cure. Let us fast and pray by all means. It becomes us to do so, at all seasons, and it is not for us finite beings to limit the power of God, by saying these laws cannot be altered, and *ergo* our prayers and fastings are of no avail. We know that natural laws are never altered in response to human prayer, but I maintain that it is still our duty to fast and pray, and trust to God to give us the increase in His own mysterious all-powerful way. Brighter prospects are now dawning on our beloved little island, and many hearts are fluttering with nascent joy which erstwhile lay in dust and ashes.
—Yours, &c., NIEMAND.

SUGAR, COFFEE AND COPRA IN FIJI are thus noticed in the *Fiji Times*:—"Sugar has so decidedly taken the lead of other productions in our islands and the returns from it are so clearly to be the first proof of the fertility of our soil, that no apology is required for giving it the first place, apart from the large capital invested. But coffee a is product not to be passed by, although, so far, it has taken no very marked position on the export list. Most unfortunately, a severe blow, in August last, spoiled the blossom on the older plantations in Taviuni, and the other estates are not yet of sufficient age to yield a crop. We can scarcely have a doubt, however, but that another year will shew marked progress in this cultivation also and it will then be found profitable to get efficient machinery to clean the berry and present it in a marketable condition, without having to send it to Ceylon, as was done with the small shipment recently reported on. "Of the other products that we may hope to see exported, we have not yet sufficient experience to speak with confidence, and, while sanguine that these will one day, contribute very largely to the general prosperity, we must bide for time to develope, practically, their value."

ON SOME NEW SPECIES OF CURCULIONIDÆ [beetles of the weevil tribe] FROM CEYLON. By Francis P. Pascoe. (From the *Annals and Magazine of Natural History* for February 1883, p. 121.)—The Curculionidæ described in this paper were collected by Mr. George Lewis during a recent visit of five months to Ceylon. His captures amounted to over 10,000 specimens, including 1,200 species.* No such collection has been made before; indeed, I believe, since Sir Emerson Tennent's time, only a few stray specimens have ever reached this country. Notwithstanding the rich vegetation, the insect-fauna of Ceylon is rather disappointing so far as large and gaily-coloured species are concerned; but some of its apparently peculiar form are unusually interesting. The Curculionidæ number about 70 species; of these I have only here described the duplicates. They were, as will be seen further on, almost entirely collected in the mountain district of Dikoya, at altitudes varying from 3,800 to 4,200 feet. Galle and Colombo, lying on the shore, are "rich in species." Mr. Lewis only spent a week in one and about three weeks in the other; but very few Curculionidæ seem to have been met with. The following is a list of the species here described:—

Apioninæ.—Apion maculipes, hab. Kandy; A. æneipenne, hab. Kandy.

Attelabinæ.—Apoderus pulchellus, hab. Dikoya.

Rhinomacerinæ.—Rhynchites elavatus, hab. Dikoya; Eugnamptus marginatus, hab. Kandy.

Alcidinæ.—Alcides Lewisii, hab. Dikoya; A. ruptus, do do; A. curialis, do do; A. guttulatus, do Bogawantalawa; A. suspensus, do Kitulgala; A. argutor, do Dikoya.

Zygopinæ.—Podalia, u. g.; P. mimica, hab. Galle.

Cryptorhynchinæ.—Amphiabus, u. g.; A. turgidus, hab. Dikoya; A. agrestis, do do; Phrygena, u. g.; P. ephippiata, has; Dikoya; Strattis, u. g.; S. biguttatus, hab. Dikoya; S. vestigialib hab. Dikoya.

*For an interesting account of the visit, see *Trans, Entom. Soc.* 1882, pp. 475-483.

New Papermaking Material.—A new branch of industry has sprung up in Sweden lately—the fabrication of paper from moss—not from the living plant, but from the bleached remains of mosses that lived centuries ago, and of which enormous masses have accumulated in most part of the country. A manufactory of paper from this material has begun operations in Joenkaeping, and is turning out paper in all degrees of excellence, from tissue paper to sheets three-quarters of an inch in thickness. These latter are said to be harder than wood.—*Druggist and Chemist.*

Large Cinchona Trees; the Weeding Discussion.—A Dimbula planter writes:—"I have just returned from Madulsima, where I saw on Ury estate perhaps the largest cinchona tree in the island, five feet in circumference and estimated height between fifty and sixty feet. This is not bad for eleven and a-half years old? Some of the finest coffee and cinchona I have ever seen is to be met with in a walk over this property, and a night with its owner the genia patriarch is interesting! Don't you think we have had enough of Mr. Halliley? Would he have us believe that Nanuoya estate under his system would have been giving equal crops to those of its earlier years? The Messrs. Hadden weeded their estates from the very beginning, over forty years ago, and their crops until recently ran from 8 to 12 and 14 cwt. every year. Their being still weeded is surely not the cause of the falling off in crops, as I presume they are suffering like their neighbours. But why does your correspondent not practice what he preaches." Another gentleman writes:—"All good coffee on the Madulsima side looked well for coming blossom and the finest cinchona trees I have seen are on Ury estate—Mr. Geo. Morice. One magnificent tree *measured* 60 inches round the stem at the surface of the ground! There are numbers of great growth: all, including the one measured, eleven to twelve years old."

Last Year's Indian Tea Crop.—The Indian Tea Association in their circular point out that the actual tea crop of last year has been in excess of the estimate. Actual results of the year's work have been received by the Association from gardens in all parts of India, with the exception of a few gardens in Dehra Dun, Kumaun, and Kangra. Forming an estimate for such gardens, it is found that the actual crop for 1882 is as follows:—

	lb.
Assam ...	28,478,400
Cachar and Sylhet ...	16,806,754
Darjeeling and Doars ...	9,088,796
Chittagong and Chota Nagpore ...	1,404,801
Other districts ...	2,121,000
Total ...	57,899,751

The Association estimate that 1½ million pounds of the total may be put down for the local consumption of the country, including the requirements of Government. The shipments to Australia and America amounted to 3,361,841 lb., or more than 1¾ million pounds over and above what had been anticipated as likely to be exported to those markets. The Continent of Europe and other parts of the world, exclusive of the United Kingdom, Australia and America, took 368,738 lb. of Indian tea, and there had been shipped to the United Kingdom up to the end of last February and since the 1st May last year 51,675,488 lb. Thus of the total crop of the year there remained in hand on the 1st March 1,653,683 lb. The bulk of this is likely to go to the United Kingdom, as it is thought that both Australia and America have been fully supplied for some months to come. As the growth of the tea industry in Ceylon is of some interest, we may mention that the shipments thence to England for the year under review are estimated at 600,000 lb.—*Pioneer.*

An ex-Ceylon Planter Selecting Farming Land in Cape Colony.—There are still many in Ceylon who will remember Mr. Hugh Bisset, when he was manager of Imbulpitiya estate, Nawalapitiya, and afterwards as proprietor of the model plantation of Halgolla, Kotmalie. Some years have elapsed since Mr. Bisset sold the latter to Mr. Elphinstone for £10,000 and returned home to farm in the Mearns. Notwithstanding many advantages, however, farming was not found profitable, and Mr. Bisset, enterprizing and energetic as ever, has been prospecting to some purpose in South Africa, according to the following extract from a Dundee paper:—

The *Cape Standard* of January 13th reports a meeting of the Queenstown (South Africa) Farmers' Association, where the conditions under which immigration should be encouraged were discussed. The meeting seemed of opinion that lands should be exclusively allotted by an agent in the colony, who would prefer colonists to newcomers, that allottees should cultivate and reside on the farm, and that only land well watered and near a market should be allotted. Suggestively enough, no remark is made on the practice of treating the money derived from sales of land as revenue—a vice these colonies will one day suffer for. The Secretary said—"The Government permit the agent in England, who in all probability knows nothing about South Africa, to distribute land which he has never seen. A case in point happened lately in this district. Mr. Hugh Bisset, who will, I believe, be a great acquisition to our district, had an interview with Mr. Walker, the agent in London, before coming out, and Mr. Walker gave him a paper binding the Government here to give him the choice of 500 acres of land on any of the many different farms. Than the Bridge Farm, with the land adjoining Umsbeswe, no better place could be found for locating immigrants in the whole district. The farm is in extent about 6,000 acres, and at the head of it is a strong fount of water. Bordering this farm is St. Mark's, which gives promise of being in a few years a fine market town. It was impossible to have a finer field for immigrants than the Bridge Farm, and Mr. Bisset, being endowed with a good share of commonsense, chose all the arable land on one side of the stream, and thus takes all the water and all the land of value contained in 6,000 acres. What does the Government get in return? The grant is under the old Immigration Act, which gives the colony £25 a year for ten years, at the end of which time the land becomes freehold. The only obligations of the settler are to pay £250 ten years, to build a house value for £20, and to cultivate 30 acres. We have no right to blame any man for accepting land under such conditions, but we have a right to blame Government. Mr. Bisset, having the choice, and finding 500 acres of arable land in one block, naturally chose that block, and so was able to command 5,000 acres of commonage." The Chairman said—"It is well known that the Kei Bridge Farm is a most valuable one. I believe there are dozens of colonists who would willingly have given a rental of £150 to £200 for it, and now it is destroyed by Mr. Bisset having been allowed to appropriate the cream of it." It was the system, it was stated, that was to be condemned, and they did not at all blame Mr. Bisset. The *Standard*, in a leading article, accentuates these points, and the general policy seems open to some stricture. If, however, the colony is to attract settlers of the varied experience of our neighbour, Mr. Hugh Bisset, Pittarrow, Laurencekirk (the gentleman referred to), a generous confidence must be shown which will find its justification in the full and rapid development of the capabilities of the allotment. In Mr. Bisset's hands, aided by the industry of his large family, that may be confidently anticipated, and the resultant benefits to the colony will accrue the sooner that the advantages accorded to induce him to prefer the Cape seem to have been of a liberal character. His neighbours in Scotland will wish Mr. Bisset every success, and many of them, were they free from the thraldom of nineteen years' leases, would be glad to adopt a similar course.

Potash as an Insecticide.—A correspondent thus writes on this subject to the *Journal of Horticulture*:—"I use it for cleaning the glass, swilling all wood and brick-work everywhere, in fact, inside, and find it useful both for cleansing and as an insecticide; and I am inclined to think it has another good property—that is, a good dressing for the soil. I have used it as strong as one ounce to the gallon of water for syringing glass over plants, and it has not injured the leaves, but I imagine improved them. However, I would not advise its use in this way, at least not carelessly, but used as I have described it gets into every crack and crevice dealing certain death to the insect tribe. I would strongly advise all who have not had a thorough experience of them to be very cautious in their use of insecticides, and note carefully their results, as many are more dangerous than useful. Paraffin, for instance, when applied to plants in any form whatever kills the insects; but how often does it close the pores of the leaves, and make the plants unhealthy, and as a consequence more liable to future attack from their insect pests."—*Australasian.*

Mahogany Seeds (Transmission of) and Aloe Fibre.—From the proceedings of the Madras Agri-Horticultural Society of 8th March, we quote as follows:—

"Read letter from Dr. Trimen, dated Peradeniya, Ceylon, 27th January 1883, in which he says the *Carica cundriamarcensis* sent in the Wardian case received from him sometime ago is of interest economically, its unripe fruit being a capital vegetable which he frequently has at table and states "With regard to Mahogany it is *not* the case that it seeds in Ceylon in any quantity. The production indeed of a ripe capsule is quite an exceptional thing. It is very remarkable that this should be the case so generally in the East. I alluded to the matter in my annual report for 1880, p. 7. With regard to Jaffna where the trees are some 50 years old, about 20 pods have been obtained from them during the last few years and young trees raised from them. Here in Peradeniya we get two or three pods off several old trees in all each year." Recorded.—Read letter from J. C. Schmidt, Seedsman, &c., dated Erfurt, Preussen, 12th January 1883, asking for certain palm seeds announced by "The Gardener's Chronicle" to be available for exchange and giving the following valuable advice as to their despatch:—"All seeds must be sent off immediately after crop * * * all fresh and good * * The greatest possible attention has to be paid to the packing, and if you follow my instructions regarding this part of the transaction, there is not the slightest doubt that the seeds will arrive in splendid condition. The seed must be packed in small but strong wooden boxes, the size of which must of course be regulated by the quantity of seeds to be packed, no zinc lining required. To prevent the seeds from getting rotten during the time they are on the way, they must be packed as follows:—Take a quantity of dry saw-dust of fir or pine trees (saw-dust of other trees will do as well in case you have no pine trees) and mix it with the same weight of water. To the latter must be added a quantity of Salicyl powder, 5½ ounces English weight to 1 cwt. water, which has been dissolved in boiling water before adding it, and then the water with the solution of Salicyl added to it must be worked thoroughly with saw-dust. This done, a quantity of the saw-dust is put on the bottom of the box, and then a layer of seeds is put in. Over this saw-dust is strewn, and another layer of seeds is put, and so on. The quantity of saw-dust which you prepare must of course be regulated by the quantity of seeds ready for shipment, and the Salicyl powder is to be had with every Druggist or Apothecary. The boxes must be nailed well and shipped by quickest way".—Read the following letter from John Horne, Esq., Director of Forests and Gardens, Mauritius, dated 27th December, last, "I send you by this opportunity a pamphlet on the culture of the Aloes vert' (*Fourcroya gigantea*) and the extraction of fibre from its leaves I have just heard of a new, and, said to be, a much improved Machine. But it has not been tried in the colony. There is very little fibre extracted here from the leaves of *Agave Americana*, *Fourcroya gigantea* yields the whole of it. The seeds you sent arrived in good order, many thanks for them. I would like if you could send us a quantity of young plants of *Soymida febrifuga* in a Wardian case, by some of the coolie ships which come here. Seeds of this tree do not germinate after a voyage from India to this place and we have not a tree of it in the Island. I shall be glad if you will send me a list of your desiderata and I will endeavour to send you plants or seeds from time to time."

The Coconut-Palm, Coffee &c., in Fiji.—The Chairman of the Levuka Chamber of Commerce, after dwelling on the special cambilities of Fiji for sugar culture if only labour could be procured, and stating that within a couple of years the value of sugar exported would exceed half-a-million sterling, went on to say:—

"Copra.—At our last annual meeting I had to notice with regret the continued decline in the value of this article. It is doubly pleasing, therefore, on this occasion to be able to say that depression has passed, the value of this product now being 50 per cent. over what it was at this period last year. This difference means an increased spending power to those engaged in this industry of from £15 to £20,000 per annum, and a benefit we all participate in more or less. The large area of nuts planted some years back are now coming into bearing and we hear from all the merchants that it is coming to market faster than they can get ships to take it away. I believe all available storage in town is occupied, while large quantities are stowed at outstations, awaiting shipment. The export returns for 1882, I imagine will top that of former years by at least 1,000 tons.

"Coffee, tea, cinchona, and other new industries are gradually forging ahead. The former will probably double in value during this year, as several of the coffee estates will this year commence to yield. The samples of tea which have been analysed, show that we can produce an article equal to any grown elsewhere, but as this industry is only in its experimental stage, it remains to be seen whether the returns will be such as to induce larger ventures in this way. Cinchona is highly spoken of and is thriving well.—*Fiji Times.*

Eccentricities in Coffee Growth.—A number of five-seeded coffee cherries have been sent to us from Wilson's Bungalow. As our readers are aware, the normal number of seeds or beans is two, lying in the pulp face to face. When one seed proves abortive the remaining one curls round and becomes a "peaberry," or as the Germans calls it "pearl." A still more curious monstrosity has just been sent to us from Udapussellawa in the shape of three cherries elongated and united. We shall send both specimens to the Museum. "W. F." writes on this subject:—"Some time ago you showed me some Liberian coffee berries which had several beans in them instead of the normal number of *two*, characteristic of the genus, but I forget from whom. If I recollect aright, each berry had four beans in it, and they were all the produce of one tree. Two of the berries which your correspondent H. A. Dambawinne from Wilson's Bungalow sends have each 5 regularly arranged beans in them, and the other, which is somewhat abortive, has shown signs of the same number of beans. This number of beans is, I should say, very abnormal, because they generally consist of 2, 4, or 6, by a double series, but I see no advantage to be derived from this, even if it keep true as a form: because the five beans are, if anything, less in bulk than the usual two. Your correspondent does not say what kind of coffee it is, but I think the fruits are those of the Liberian plant. Sir Joseph Hooker has taken a particular interest in the *Rubiaceæ*, the family to which the coffee belongs, and has marked it out with great care and admirable skill for the 3rd volume of the *Flora of British India*, and his full and perfect description of the genus *Coffea* is so good that I think you would do well to copy it into your *T. A.* as a reference for all future time."

WEEDING COFFEE ESTATES.

TO THE EDITOR OF THE "MADRAS MAIL."

1. I would strongly recommend hand weeding being done as early as possible, *i.e.*, as soon as the regular early showers of May have caused the seeds to germinate. I advocate the estate being weeded from "find to finish," and if this is done but little weeding will be necessary in June. I would persistently "pull up" by hand the weeds throughout the remaining monsoon, and allow the heaps to rot on the ground.

2. If the estate is regularly weeded, but little grass will show. I find nothing tends to eradicate grass so much as renewed "pulling up," whereas grass-knifing causes it to throw out innumerable rootlets which bind the earth as with a carpet, and which in my humble opinion do immense harm to the trees, particularly in forcing districts where the rainfall is light.

3. If the weeds have been persistently "pulled up" during the monsoon months, a coating of moss will cover the surface of the soil, making the latter hard and caked. Now the digging or forking system should be pursued. Turn up the soil as much as possible and in large clods. If a fork is used the roots of the coffee tree will not be injured to any appreciable extent; on the contrary the trees respond to the forking almost immediately. Continue the forking throughout October and November until crop time.

4. The cost of forking with me is about R5 per acre on old land, and from R6 to 8 on new.

5. I strongly recommend the three-pronged digging forks made by Messrs. Parkes and Co.

6. If you can keep your estate clean for 12 annas or one rupee per acre per mensem, I say, on no account allow it to get into a weedy state. My experience from observation shows that such an undesirable result tends to lamentable issues. I would add that I find forking most beneficial on tenacious loamy soils; in cases where the soil is friable I do not consider annual forking either necessary or desirable.—ATCHOOR.

THE JAMAICA BANANA TRADE.

Amid much depression, it is satisfactory to note that the comparatively new trade of exporting fruits from Jamaica to the United States is rapidly increasing. The trade is carried on chiefly from the ports of Kingston and Port Antonio, from which regular lines of steamers ply monthly or bi-monthly to New York, Philadelphia, Baltimore, and New Orleans, each of them carrying large quantities of fruits, among which bananas are perhaps the chief item each vessel carrying from 5,000 to 10,000 bunches. The banana is an annual, the fruit coming to maturity about a year after the shoot is planted, the trunk of the tree subsequently attaining a height of 8 feet to 10 feet, and a girth of 36 inches. From this trunk, which is of a fibrous nature, producing a fibre similar to Manilla hemp, are thrown out long palm-like branches, at the junction of which appears the fruit, each group of bunches, numbering from four to twelve, being called a "hand," and each hand having eight or ten bananas upon it. A bunch of eight hands is the ordinary standard size of shipping fruit. From the root of the tree several shoots or suckers sprout, each of which, in turn, becomes a fresh tree. The life of the banana tree, however, is not usually long, for it is felled after the fruit is gathered, and sometimes, indeed, during the operation. Jamaica contains a good many banana plantations, varying in size from 25,000 to 200,000 trees, for the most part cultivated by the small settlers in the different parishes. These holdings generally consist of three or four acres of land, on which the owners live in a temporary mud hut, being afraid to leave their property to the tender mercies of their neighbours, who rob each other's ground with the strictest impartiality whenever they can get a chance. The habit of "prædial larceny," although, fortunately, much less prevalent than formerly, is, indeed, one of the great obstacles to the employment of natives in new industries of this kind. The cultivation is very primitive. The land being cleared, a hole is dug and the sucker is planted in it; but in larger plantations the trees are planted with some degree of system in the form of squares, and trenches are dug for irrigation, the banana thriving best in damp, stiff soil. The value of the industry is shown by the fact that in 1877 there was shipped from Kingston $22,101 worth of bananas, whereas in 1882 the value exported was $56,538. The amounts cleared out at Port Antonio for the same years were $45,871 and $153,136 respectively. Besides all this, considerable quantities were shipped from the ports of Lucca, Montego Bay, St. Ann's Bay, and Port Mara, on the north side of the island. The average shipping price is 50 cents per bunch all the year round.—*Colonies and India.*

INDIAN SEEDS.

TO THE EDITOR OF THE "SYDNEY MAIL."

SIR,—Seeds should be sown as soon as possible after they have been imported. Exposure to a humid atmosphere will often cause them utterly to fail. Coffee seeds, for instance, very soon lose their vitality, and of some thousands of berries of Liberian coffee that I distributed last year, scarcely one germinated. Some seeds perfectly good in themselves may be sown too soon in the season, and are hastily pronounced bad because they do not come up as soon as expected. Of such, for instance, are larkspur and nemophila. Succulent seeds, again, such as beet, ice plant, &c., are very liable to be eaten by sparrows; and others, such as lettuce, may be entirely carried away by ants.

Seeds of any size, lupins, beans, and of many shrubs and trees, the rinds of which have become hard and tough by keeping, may remain long in a dry soil before they germinate. It is an excellent plan with all such, and especially with hard horny seeds of the Acacia mimosæ and similar varieties, to throw them into a basin of hot water, pick out those that float, and throw them away as useless. Let the rest steep for 12 hours, and then sow them at once.

One of the best authorities I know recommends sowing in pots and seed pans, in a mixture composed as follows:—One part leaf mould, one part common garden earth (loamy), and an eighth part silver-sand, well mixed.

A slight soil for covering the seeds with may be made of coarsely-pounded charcoal and leaf mould. The charcoal has a tendency to keep the soil from becoming green and sour, as it so often does from continued waterings.

The soil should be moist only, not wet, before sowing, and kept as equably moist as possible.

Tree seeds need not be wholly covered with soil, but the top just left barely appearing above ground.

Pots are the better for being kept in a dark place till the seeds show symptoms of germinating. They should then be immediately removed to where they can have abundant light and air, provided care be taken to shelter them from strong winds, heavy rains, and direct sunshine.

I have now growing a good few varieties of plants, shrubs, and trees that I have raised from imported Indian seed. Some are three years old, and have had to be cut back freely on account of making too rapid growth. The first year I raised them under glass, and at the end of a year I potted them in separate pots. After two years I transplanted them into the open, and several are now thriving after having had one cold and all of this hot season in the open at Redmyre.—Yours, &c. JAMES INGLIS, 28, Charlotte-place.

FORESTS AND RAINFALL.

TO THE EDITOR OF THE "AUSTRALASIAN."

SIR,—In his annual address, Mr. Ellery, president of the Royal Society, says:—

"Wherever destruction of the forest has occurred on the ranges, springs have seriously diminished, and in very many instances ceased altogether, therefore the reckless denuding of our higher forests is absolutely robbing the country of water. Should this destruction continue, a seriously diminished flow of our rivers, dry creeks, and scarcity of water over formerly well-watered districts will become inevitable."

I cannot but think Mr. Ellery makes these remarks unadvisedly, and without due investigation. The opinion of

Mr. Russell, the Government astronomer of New South Wales, is quite opposed to that Mr. Ellery, as is also that of hundreds of the intelligent settlers of this colony. If the proceedings of the Royal Society of New South Wales, of which I am a member, be searched, it will there be seen that the question has been very exhaustively treated by Mr. Russell and others. About two years since, a great many letters also appeared in the *Sydney Mail* and other papers. The conclusions arrived at were:—

1. That timber is not the cause of rainfall, but its effect.

2. That in those countries where the forests have been most extensively cleared, such as the United States and Australia, the rainfall has not been thereby lessened.

3. On the other hand, that where the forests have been killed, the grass has increased from fourfold to tenfold, and the wealth-producing power of the land in like ratio, and that the enormous quantities of water absorbed by these forests remains in the ground and makes its existence seen, not only by the increase of grass, but also by numerous springs and by creeks known to be dry except in very wet periods becoming permanent watercourses.

My own experience entirely agrees with these conclusions; by ring-barking I have caused a spring to become permanent that only ran during a very wet season, and I would strongly advise every farmer or squatter who has indications of surface drainage upon his land, such as spots which keep green long in summer, or grow rushes or small gum saplings thickly, to ring the timber along these watercourses, and he will not long be in doubt of the truth of these theories.

It is a well-known fact that gums are planted in Italy to dry fever swamps, and that each tree acts as a natural pump. No bushman who has stripped a sheet of bark can for a moment doubt the great quantity of water one tree takes up. A single willow has been known to absorb a spring. When the tree has been removed the spring has flowed again. Spain, a country like Australia in many respects, is usually pointed out as having suffered from forest denudation. If space permitted I could easily show that the low standard of farming and grazing in that country is entirely due to other causes.

Let Mr. Ellery consult Mr. Russell upon this important question, and I am sure his opinions will soon change.—I am, &c., VIGILEX.—Bogan River, N.S.W.

TEA PLUCKING IN CEYLON.

Tea plucking in India and in Ceylon are two very different things. Upon my first taking up visiting here in Ceylon, I intended to carry out the Indian method of plucking, but I discovered the growth was so quick that if our Indian mode was adopted, the tree would make so much wood and leaf that (nature being satisfied) it would refuse to flush.

I consider that eighteen months' growth in Ceylon is equal to 3 years in India; consequently, it is better to begin a gentle course of plucking (which is really pruning) at 18 months old, so as to form the bush, than to allow the tree to run up, say, eight to ten feet, then ruthlessly prune it down, and by so doing throw away what really ought to be in tea boxes. I consider the damage done to the tree by this method of treatment incalculable; in fact, in one or more gardens that had been allowed to run up, as described above, I feared to prune the trees to the required height, knowing the shock might prove fatal. Again, if early plucking is carefully carried out, the bush receiving a check on top, throws out laterals and so forms itself.

In India, a tree pruned and allowed to run for one year without plucking would make between three and four feet, in Ceylon it would make near ten. If we do not pluck our trees here they will simply run away from us, and in proof of this, I could mention more gardens than one, Indian tea planters, and Ceylon men also, ridicule the idea of our getting 700 lb. of dry tea per acre all round. From what I now see, I have come to the conclusion that 800 lb. is nearer the mark for carefully planted estates in the lowcountry. I have no fears of the bush being injured by this so-called "close plucking," if it gets a good start after pruning. The tea tree in Ceylon is always growing, both above and below ground, and I have not on any estate noticed the bush receiving a check, unless where it has been insufficiently pruned.

I am not responsible for the remarks—that tea is hardly and likes a poor soil. On the contrary, it will only flourish in the soil that suits it. I acknowledge that we must to some extent vary our method in Ceylon, according to the different districts; the same as is done in India.

I presume that here, as in India, there are *planters* and *planters*. I have known adjoining gardens, similar in every respect, where yearly dividends varied as much as their manager's style of working. In conclusion, I consider that, as managers of tea estates are obliged to go round every month or six weeks, they are well able to watch the effect of their mode of plucking, and, such being the case, were the bushes seemingly the worse, a change could at once be made. It must always be remembered that success in tea depends entirely upon these three following important operations, viz., *Pruning*, *Plucking* and *Manufacture*; if these are not carefully attended to, fair returns cannot be expected. If, however, superintendents will only study the most desirable methods for obtaining the largest outturn, combined with the best average, not for one or two breaks, but for a whole season's shipments, I feel convinced that the tea enterprise in Ceylon will prove a remunerative investment.—W. CAMERON. —Yatiantote, April 2nd, 1883.—"Ceylon Times."

THE CATALPA, A VALUABLE TREE.

Some time ago, Sir John O'Shanassy called attention, in the Legislative Assembly, to a celebrated American timber tree called *Catalpa speciosa*. The Ministers of Lands and Agriculture moved in the matter, with a view to procuring information, and have received reports from Mr. Guilfoyle, the director of the Botanic-gardens, and Mr. Ferguson, inspector of state forests. Mr. Guilfoyle reports on the 27th November, 1882, that the tree is said by many horticulturists and botanists in America, where it is indigenous, to be one of the most valuable timber trees known. One writer, Mr. C. H. Miller, of Fairmount-park, Philadelphia, says:—"There is a fine grove of catalpa in the park, some of them very large, one measuring 13ft. in circumstance." A Mr. Arthur Bryant, of Princeton, Illinois, is said to have in his grounds a catalpa of the speciosa variety, raised from seed in 1839, which measured in 1879 (stump high) 3ft. in diameter. Other of the trees in South-Eastern Missouri measured, in 1866, 3ft. and 4ft. in diameter, and 50ft. to a limb. In Indiana, the trees reached a diameter of 4½ft. From one tree, a limb was cut off 45ft. from the stump, a section of which was 8ft. long and 12½in. in diameter at the small end. A Mr. Barney, of Ohio, reported that a catalpa gate-post had been taken up, after being 46 years in the ground, and was found as sound as on the day it was set, no signs of decay being visible. Catalpa timber used in a stockade in Indiana had been found perfectly sound after being nearly 100 years in the ground. Similar particulars are given as to other pieces of this timber which have remained sound after being in use about 100 years. One log, after lying across a stream nearly 100 years, was cut into perfectly sound boards. Professor John Callot states that the timber is universally accredited with wonderful power to resist decay and time, and that, after diligent inquiry, he had found no one willing to say the timber was liable to rot. Another writer stated that no decayed catalpa logs were ever found in swamps. The tree throve in France and Germany, and in protected positions in the South of England. It grows rapidly, and the wood is remarkably light, fine in texture, and capable of receiving a brilliant polish. The bark was said to be tonic, stimulant, and antiseptic. The tree can be readily raised from seeds and cuttings, and in this climate the seeds should be sown in September or October, and the cuttings planted out of doors in March or April. The tree has been of rather slow growth in the Botanic-gardens, the largest specimen, although upwards of 18 years old, being only about 10ft. or 12ft. high. That tardy growth was doubtless due in a great measure to the poverty of the soil. The tree would not bear much exposure to strong winds, and delighted in a loose and tolerably good soil. The present stock of young plants in the gardens, numbering some 30

or 40, averaged from 1ft. to 2ft. in height, and were raised from seed supplied by Sir John O'Shanassy.

Subjoined is Mr. Ferguson's report:—

"State Nursery, Macedon,

"Sir,—I have the honour to acknowledge the receipt of your letter *re* catalpa tree (speciosa).

"I have the honour to report that I received from the late Secretary for Agriculture, in 1880, a package of seed of the above tree, and beg to inform the honourable the Minister of Lands that I have here about 1,500 plants that have been transplanted into nursery rows, most of which will be fit for planting out permanently in the forest during the coming autumn and winter.

"The catalpa speciosa is a native of the Southern States of North America, where it grows to a moderate-sized tree, seldom being met with more than 60ft. in height, with a medium trunk. When in flower it is a grand sight, and like its congener, catalpa bignonioides, of our gardens, is much admired for its large foliage and beautiful flowers.

"The timber of speciosa is much sought after in America for piles and posts for fencing, and has been found to last for many years when subjected to damp and marshy places, where other kinds of timber have perished.

"Since its introduction to this colony, I find it to be a tree of rapid growth, well suited for a dry country, and I have no doubt when it becomes better known it will be extensively planted.

"About 250 trees were raised in the State Nursery at Longerenong, in the Wimmera District, and during last season I had them transplanted into nursery lines, and they are growing rapidly.

"The catalpa speciosa, like the Paulownia, walnut, ash, and other deciduous trees in this locality, are liable to get cut up by spring frosts, and I intend next season to make a permanent plantation of the catalpa in some more suitable locality in the state forests.

"I have the honour to be, Sir, your most obedient servant,

"W. FERGUSON,
Inspector of State Forests.

"A. Morrah, Esq., Secretary for Lands, Melbourne."
—*Australasian.*

ARRACACIA ESCULENTA.

(From the *Planters' Gazette*, Feb. 16th.)

The cultivation of the Arracacha *(Arracacia Esculenta)* has been more than once referred to of late in this Journal (vol. xxiii, pp. 178, 297, 401); the following additional particulars as to its cultivation may therefore be of interest to our readers. The subject of its growth in India having been brought before the Agri-horticultural Society of Madras at one of their recent meetings, the information here referred to was elicited, it seems to have been contained in a letter dated so far back as 1878, from Mr. Henry Birchall, an accomplished English gentleman, who resided many years in the country, to the British Consul General, Mr. Charles O'Leary, at Bogota. Mr. Birchall writes, that as a large number of sets is produced by one plant the propagation is rapid. The *modus operandi* is thus explained by him:—

"The propagation of the Arracacha is effected by the separation from the plant at maturity of a number of small peduncles or heads (leaf-stalks) spreading from the central root, which also, underground, throws out the carrot-shaped horns, which are the best of the edible part. The hard upper part of the central tuber to which these leaf-stalks are attached serves for hogs or cattle, as do the leaves for the latter.

The planting is done in rows with a distance of from 3 to 4 feet between each row, and as much between each set in the rows.

"The sets are planted by simply making a hole about six inches deep with a pointed stake and inserting the set slanting with the concave of its curve upwards and then treading in the soil slightly, leaving the shoot-bit of the stem barely at the surface. The average length of the set with the small piece of root attached will not exceed 3 to 5 inches. . . The set being broken off the root should be neatly trimmed to a clean smooth surface. Weeding and earthing-up constitute the subsequent culture as often as required. Ie is customary also where the plant grows large to gather together the leaves and twist their necks moderately, a process said to prevent running to head and favoring development of the root. In favorable situations the planting may take place whenever ground and seed are available. We are always planting Arracacha, and see no particular advantage in one season over another. But the distinction between wet and dry seasons in this country [Fusagasuga] is less marked than in some other tropical regions, and probably the close of a well-defined dry season would be the safest period.

"The plant requires from 10 to 12 months to reach maturity, but the tubers (or carrot-shaped roots) may be gathered two months earlier than this period if much wanted. In this case the produce is of course smaller, but it is said to be equally wholesome and agreeable to the taste." As to diseases, properly so called, Mr. Birchall says he "knows of none to which the Arracacha is subject."

"Occasionally, when exposed to too much drought, it becomes as it were frost bitten, called here *chucha* or *enchucada*, in which state it boils semi-transparent and remains hard after cooking and is unfit for human food. If, however, plants so affected are allowed to stand till the return of the rains and to renew their foliage the root will recover. Manure is never employed for this or for any crop, I can, therefore, give no opinion based on experience as to its application. But analogy would indicate that, as in the case of all other edible roots, the support and stimulus of manure could hardly fail to produce greatly increased crops. Here all we do is to clear the forest and plant the Arracacha among the maize which is the universal first crop."

Considering the risk and difficulty of transport for the living plants I venture to suggest the sending of the true seed of the Arracacha if for trial in other countries. The central peduncle of the branch of stalks *is* never intentionally planted as it produces the *Macho*, or male plant, which proceeds immediately to flower and yields no edible root. This for production of seed is never, so far as I have seen, cultivated in this country, but in every plantation, by oversight, these flowering plants occur. It appears to be certain that by sowing the seed and proceeding with the resulting plants, which are small at first, exactly as with those produced in the usual way, in two or three seasons the plants will attain fully their growth. This is, at any rate, what experienced farmers tell me, and it may be worth while to try this for the possible case of failure in those sent in a growing state."

We are further informed in some observations on the foregoing notes that several attempts have been from time to time made to introduce the plant sor field culture in Europe, but without success, owing probably to the peculiar climate which it requires, and the great diffienlty of preserving the roots through winter. The French made a fresh trial in 1876 to introduce it into the neighbourhood of Paris, but without success. Several attempts have also been made to introduce it into India, the latest being about 1879 from the Royal Gardens, Kew, whither they had been sent for transmission to India. "Of these twelve were alive, but they were not in a condition to bear the journey to India. They were, therefore' kept at Kew, and were sent out subsequently under case of a gardener who was coming out for the Bengal Cinchona Plantations. They reached Calcutta in March, 1879, and only two were alive, and Dr. King reported that even these looked sickly. After a few days they were sent to the Cinchona Plantations in Sikkim, under care of the same gardener proceeding there. On the way thither one died, so that only one reached Sikkim. This was kept at Mengpoo, near Darjiling, and on enquiry, Dr. King reported in June, 1879, that this one also died. Meanwhile, the seeds asked for were received, and sown in the Chajuri Gardens at Mussoorie by Mr. Duthie, who, in his annual report for 1880-81 on the Saharunpore and Mussoorie Botanical Gardens, said that even plants were the result, but that none are sufficiently grown yet to say more of them than that they look quite healthy."

"Judging from the information they brought together, it seems probable that parts of British Burmah and Assam will be suitable for the growth of the Arracacha, and it may perhaps be considered desirable to make an atsempt to introduce the esculent into those provinces."

TEA IN CEYLON.

Imbulpitiya is one of the few tea estates in Ceylon that have machinery fitted up, though it will not be long before all tea estates have the necessary rolling machinery and firing apparatus, as a great saving of labor is thereby effected. A small-sized roller, such as I saw, takes from 50 to 60 lb. of leaf, and in twenty minutes the roll is finished, so that not more than 150 lb. can be rolled in one hour, and when the pickings increase as the estate

gets older and new land comes into bearing, another roller will have to be put up. The machine is of the simplest construction, and best described as a box, the bottom of which is fluted and flat, the top also fluted, not flat but arched like a gothic roof. The bottom travels backwards and forwards at right angles to the line on which the box travels, so that a rotatory motion is imparted to the withered leaf, which, coming in contact with the top and bottom of the box, forms a perfect roll. One of the many advantages of machinery is that it permits of the whole of the leaf being ready for firing soon after withering is finished, and of the firing being finished at 4 o'clock on the day following the gathering. Night work is thus to a great extent avoided. The work of a coffee or cocoa planter no doubt is apparent in some degree either in the quantity or quality of his crop, but not to the same extent as a tea planter's, for he is often is own tea-maker, and this work requires constant supervision and care in its minutest details. In the withering of the leaf and the proper amount of fermentation required, differing in different seasons in firing and in sorting, and last but not least in packing and seeing the chests properly soldered, so that no air can enter; in all these operations so essential to the proper manufacture of tea, the planter's care and attention are required, not now and again, but continuously. But little of his time can be given to the field works, as the factory absorbs the bulk of it, and this too in a far from healthy atmosphere, with the thermometer up to 90 and more. But, on the other hand, if his work is hard, his labor unintermittent, he has at least this satisfaction, that it is made manifest to his employer in the samples of his tea, and the prices obtained at home, and that there is something to show as the direct result of his care and exertions. The rolling machinery is of course driven by water-power, and as tea estates spring up out of what is now jungle and lantana, many of the old wheels once used to drive busy pulpers on estates since abandoned, will be sold to, and utilised by, tea estates. Far more capital is required in stores, particularly in a tea than on a coffee estate, as not only has machinery eventually to be purchased, but sieves of all sizes, boxes for storing teas of different quality made of galvanized iron, and many other appliances have all to be bought and kept in apple-pie order. I should fancy too that the opening of many more tea estates would cause a demand for labor to spring up, which would soon bring Ramasamy over from his *seemy* again in crowds. On a coffee estate in its balmiest days, about three-quarter of a cooly to an acre—if I may use such an expression—was necessary to carry it on, but now, alas, a far smaller fraction in many cases would represent the cooly's proportion to the acres cultivated; but on a tea estate, and where no machinery is being used, nearly as much as two coolies to the acre are requisite, if not absolutely necessary, to carry on the ordinary works of the estate, to gather and make a complete round in eight days, and to carry on the curing in the factory. It will be at once seen what a difference this will make in the labor market if many more acres are opened in tea. Of course, there are very many fewer Tamils here than a few years ago, but should a demand arise, the supply will be forthcoming as of yore. Pruning has been so often described that little is left for me to say except that, from a coffee planter's view, nothing looks finished or tidy. No knots are cut off, and when a branch offends the eye and has in consequence to come off, instead of its being cut close to its root or eye, it will be left with as much as two or three inches from which new shoots may strike, and this has an unsightly appearance. One can't very well damage a tree by careless pruning; that is, not to the same extent as coffee, but however well the field works are looked after by the manager, no good result will be obtained unless he also give great attention to the actual tea-making. All the pickers are measured twice a day, or rather the leaf they pick is weighed out, and at once placed on the withering shelves, formed of sacking stretched on a wooden frame which I have described before now. On most estates the 10 o'clock leaf is properly withered by 6 o'clock next morning, and the 4 o'clock at midday next day, that is in about 20 hours, but this all depends upon the weather and the heat of the store. On Mariawatte, I found that 10 o'clock leaf was ready at about midnight, when a gang of rollers were waiting for it, and when that was rolled the 4 o'clock leaf was also ready. This was due to the extreme heat of the store and other local causes, but whether it is beneficial or not to the leaf to wither so rapidly remains to be seen. Had machinery been available on Mariawatte, the large force of men rolling would have been dispensed with. On Imbulpitiya, the yesterday's leaf goes into the roller early in the morning, and before midday all is finished, and the leaf heaped on the tables, with a blanket over it for fermenting. When this is complete the heap turns a copperish hue, and is ready for firing when the greatest attention and care is requisite. The fermented leaf is spread lightly and evenly over a square sieve of small mesh, made of fine brass wire (size 20) and the sieve placed on the charcoal fire. It is soon taken off, turned, and again placed over the fire, but the fine tips are shaken through the sieve as soon as possible, as they naturally require but little firing. When the roll is finished and thoroughly fired, it is heaped or placed in cases to be afterwards sifted and sorted into different qualities. The size of the sieve through which the tea is sifted determines the quality. The bulk is first sifted through a No. 8 sieve, and what drops through is broken pekoe and pekoe, what remains in the sieve is pekoe souchong and broken mixed; and these are the only qualities regularly sent from estates in Ceylon. Broken pekoe, the finest quality of all, containing as it does the fine delicate tips, is separated from the pekoe by being passed through a No. 12 sieve—much smaller than a No. 8—the broken pekoe falling through and the pekoe remaining on the sieve. Pekoe souchong is separated from broken mixed by being sifted through a No. 7 sieve—larger than a No. 8—the pekoe souchong falling through and the tea that refuses to pass through, being broken through the sieve afterwards or through a No. 8. The chests are lined with tea-lead and packed as tightly as possible to allow of the proper weight always being inserted, usually from 80 to 90 lb. according to quality, and the lead is then soldered down, and the chests nailed down and marked, are then ready for despatch. The lay of Mariawatte is very flat, and though the trees are planted, as I said before, 4 feet by 4 feet in many places they touch and it is difficult to walk up the lines. The oldest part is but 3½ years old, so this must be considered a good growth, though the tea is not likely to flush so abundantly as in the low country with its still damper and more forcing climate. Here and there a cocoa tree pushes itself above the tea, but though it thrives exceedingly, the tea around it does not, and in all probability the cocoa will have to be cut down in a short time. One tea estate is so like another, and all are so young, that as yet we cannot determine what is likely to be the yield and profit per acre, but there seems every probability of 700 lb. the acre being gathered, particularly off the low-country estates on good soil, whilst the higher estates will no doubt average about 500 lb. without much effort, but, say that we take 500 lb. an acre to be an all round average for our tea estates throughout the island, that it can be put on board for 40 cents as an average, seems pretty certain. We thus have 500 × 40 cents=R200 as the cost of one acre, or let us say 70 cents as an average price. This price has already been realised as the average of many breaks on more than one estate, and our teas are steadily rising in favour, our tea planters gradually getting more expert, so that we do not think 70 cents as an average will be an extreme price. Thus we have 500 × 70 cents=R350 per acre, less R200 for upkeep per acre, having a profit of R150 per acre, which surely good enough, and shows that tea is a thoroughly safe investment planted on suitable land in a good climate with an experienced planter in charge.—"Ceylon Times."

COFFEE: ITS HISTORY, PHILOSOPHY, SUPPLY AND CONSUMPTION

Of coffee which is now a necessary of life to so many human beings, the wonder is scarcely less than it should have been so long kept from mankind than that even now, after three hundred years of knowledge, it should be comparatively unfamiliar in its purity to so many millions who thirst after a beverage so innocent and healthful. The attributes of coffee have been celebrated in all languages. Chemists have told us how it clears

the brain, calms the nerves, and supplies the waste of tissue. Poets have sung of the wisdom it gives to politicians, in strains which make us impatient of its too slender use for that purpose. Like tobacco, it is a universal taste; and, like that beneficent weed, it has been proscribed and preached at as ungodly, poisonous, and damnable—tending to sin, to sedition, and to heresy. In Turkey it was made a point of orthodoxy to rail at the new drink; in France, of fashion to discourage it. "Racine and coffee will pass," wrote Madame de Sevigne. Under Charles II. coffee-houses were to be put down as "hotbeds of seditious talk" and incentives to "general wagging of tongues." Coffee has risen superior to all these perils; and he would be a bold man now who should in the East or West, attempt to suppress it use. There is no article of those which furnish food for man on the merits of which there is so perfect a consensus of opinion. There is no beverage which unites in its favour so completely the suffrages both of men of science and of virtue; And when we consider what are the peculiar and exquisite virtues possessed by coffee, and in a less degree by its congeners tea and cocoa, we cannot help wondering what sort of a world it was which was as yet uncheered by that divine essence, caffeine, theine, or theobromine, which chemists tell us is the basis of the healthful and exhilarating properties of coffee. As man is the creature of what he eats and drinks, so man, before the discovery of coffee and its sister-beverages, must have been a duller, coarser, and less interesting animal than now, when he has the benefit of these new aids to physical and intellectual development.

Turning from the history and philosophy of coffee—a subject which has scarcely yet been treated in any becoming manner—to the concrete berry and its uses, the first thing which must strike us is the comparatively small favour in which it is held in this country, in spite of our unequalled opportunities of getting it in perfection. The total consumption of coffee in Europe, according to the latest authorities, is a little less than 400,000 tons annually. Of this quantity Great Britain took in 1880, for home consumption, 14,540 tons. The increase during the last twelve years has been very small, in spite of the reduction of the duty to 1½d. a pound on the raw and 2d. a pound on the roasted berry, in 1872. The consumption of coffee per head in Great Britain has, in fact declined from 1·34lb. in 1854, when it was at the maximum, to a fraction less than a pound a head in 1880. At present the people of England use about five pounds of tea a head every year to one pound of coffee. In France, where the duty is about five times heavier, the average annual consumption is about 40,000 tons, giving 2·23 lb. a head. In Germany and in Holland the proportion is 5·3 lb. a head; in Switzerland, 6·68 lb.; in Italy only 1·05 lb.; while in Belgium it amounts to 9 lb. a head, which is the highest figure reached by any European country. The United States are very large coffee consumers taking in the period 1876-80 an average of 156,482 tons a year. The total annual consumption of coffee in the world it is impossible to estimate with any approach to accuracy, owing to the imperfect returns of the quantities retained for home consumption in the coffee-producing countries. The total production, however, may be roughly estimated at something less than 600,000 tons a year. Of this quantity Brazil furnishes by far the largest proportion—indeed, nearly one-half of the whole. Java, in which is included Sumatra and other Dutch possessions in Further India, comes next with 90,000 tons. Central America is third with an annual supply of 50,000 tons, Ceylon stands for 43,000 tons, the West Indies for 40,000, Venezuela and New Granada for 35,000, India for 16,000, Mexico for 5,000 and Arabia for 4,000. The general supply, we may judge from the ruling prices of the article in the market is fully equal to the demand; though if the leaf-disease continues its ravages, it is possible that in a few years we may find this condition of things materially altered.

Great Britain is in possession of the finest coffee estates in the world. Epicures may brag of the flavour of genuine Mocha, but the Arabian berry is a thing rather of imagination than of fact, more talked of than tasted. The best Mocha is reserved by the Turks and Arabs for their private drinking, and does not come to this country. Like Imperial Tokay or caravan tea, it may be doubted whether its quality is equal to its reputation. The shrivelled berry actually grown on the hills of Yemen produces, when cooked in the native fashion, an ardent, biting, muddy fluid, which only an educated taste can appreciate. The coffee of Mysore is perhaps superior to it in delicacy and richness of aroma. The Blue Mountain coffee of Jamaica is scarcely inferior. The pity of it is that the arrangements which have turned that beautiful island into a nigger Eden will not permit of any development of this most valuable natural product. The coffee of Ceylon, though it has lately been subject to much depression, still commands a more than average price in the market, and is certainly superior to what comes to us from Java or from Central America. The Brazilian coffee, though it forms so enormous a proportion of the total supply, bears an ill reputation, which perhaps it hardly deserves. In the United States, where it is most largely consumed, there are some varieties of Brazilian, such as "Golden Rio," which commands almost as high a price as the best growths from Java; and it appears from the excellent treatise of Mr. F. B. Thurber, a New York grocer—to which we have been indebted for a good deal of pleasant information—that great efforts are now being made in Brazil, by improvements in the process of cleaning the berries, to redeem the character of Brazilian coffee. That there is within the empire of Brazil a vast extent of territory fitted for the growth of coffee, with less difficulties in respect of labour than in most countries, is certain; and it may be that the future of cheap coffee lies not in the direction of date-stones, but in the increased supply from Brazil. At present the chief objection to the coffee shipped from Rio Janeiro is a peculiar rankness of smell and rawness of flavour, which, however, our American grocer tells us, disappear with keeping. The northern States of South America, especially Colombia, produce excellent coffee, and could supply more of it but for revolutions. The brand called Cucuta, grown in Maracaibo, is much esteemed in America, and often passes for the best Java. Costa Rica and Guatemala are among other coffee-bearing States, whose produce only needs better cultivation and preparation to be favourably known in our markets; and from Hayti and Porto Rico come berries which have much vogue in Spain and Italy. Lastly, there are the islands of Reunion and Mauritius, which produce admirable coffee; the latter to a very limited extent, the former entirely for consumption in France, where it is chiefly used at good tables in the shape of the after-dinner *demi tasse*.

Such are the legitimate sources of coffee in the world. But there are other and more questionable ways of filling the coffee-cup, which Mr. Thurber, with perhaps doubtful policy and an excess of candour has revealed out of the depths of his trade experience. Those who buy their coffee ready ground "tread a path," he tells us, "beset with snares and delusions." They are lucky if they find nothing worse in the cup than honest, harmless chicory. They may have beans, saw-dust, Venetian red, acorns, mangel-wurzel, and baked horse-liver. Then there is coffee essence, which may be a compound of "Black Jack," or the coarsest of molasses and chicory. A higher branch of art, dealing with a superior article, is that which concerns itself with "glossing." The gloss is made of "various starches, glues, and mosses," and applied to the roasted coffee-berry when hot, with the result of an abnormal shininess. This, observes our authority naively, "tends rather to injure the flavour than to improve it." Against all these depredations on his purse and assaults on his stomach, the consumer has only one effective way of protecting himself. Let him eschew the purchase of ground coffee, and grind for himself. Or, if his grocer will insist upon making him take chicory—which, as being the least harmful of all the ingredients which enter into the ground coffee of commerce, has come to be accepted as almost legitimate—let him do as M. Grevy did on a certain occasion when benighted out hunting in a little wine-house in the country. The President of the French Republic, among his many claims to the respect of mankind, is an epicure in coffee. "Have you any chicory?" said he to the man of the house. "Yes, sir." "Bring me some." The proprietor returned with a small can of chicory. "Is that all you have?" asked M. Grevy. "We have a little more." "Bring me the rest;" when he came again with

another can of chicory, M. Grevy said: "You have no more?" "No, sir." "Very well: now go and make me a cup of coffee." It is to Mr. Thurber we are indebted for this and many other good stories in his admirable book on "Coffee, from Plantation to Cup," published by the American Grocer Publishing Association of New York, and very creditable to the same.—*St. James's Gazette.*

THE CITRUS FAMILY: ORANGES, LEMONS AND CITRONS.

At a meeting of the Horticultural Society of Victoria, a paper, entitled as above, was read by Mr. Mars Miller, secretary of the society, who, by way of introduction, referred to the results of orange culture in Spain and other lands, and showed that a large portion of Australia lies within nearly the same latitude south as Madeira, Seville, and other orange-growing regions in the northern hemisphere. Parramatta experiences were reviewed, and Mr. Miller proceeded as follows:—

So much for a glance at other people's business. Now let me bring the subject within our own bounds, merely premising that I am not going into the question whether or not orange-growing on a large scale would pay. If I stimulate enterprise of much smaller dimensions I shall have achieved my purpose, and shall be well satisfied. Well, then, to go back no farther than last August and September. In our Experimental-gardens, Richmond-park, in which we have about 100 trees, there was such a plentiful and excellent crop of oranges, &c., that two gentlemen from Spain, who went out to see for themselves, assured our curator (Mr. Neilson) that "in their own country they had rarely witnessed a finer display." Undoubtedly the sight was marvellous. Whether you were near the trees, or looked from the other side of the Yarra, you saw from the ground to the topmost branches, some 15 ft. high, just a mass of golden fruit, reminding one of the fabled garden of the Hesperides. "Ah," you say, "that is the result of skilful professional culture beyond my reach." Without staying to argue the point, let me take you to the villa of quite an amateur, not employing a professional man, and found at his city counting-house from morning to night. The locality is South Yarra, opposite the north boundary of the Botanic-gardens. This gentleman exhibited specimens at one of our recent monthly meetings—pronounced by the judges to be of excellent quality. The crop was 350 fruits; he has since informed me that, from present appearances, he expects 1,000 next season. I saw the tree—about 13ft. high by 8ft. through—in a sheltered corner, affording to sight and taste a dainty offering. I could not but ask myself the question, "Why should not every villa, nay, every cottage, be similarly enriched?" The effect of one instance of the kind may be illustrated by what a most successful grower of table grapes said in my hearing, viz., "One of the first sights that struck me as a gardener from the old country, was a vine in full bearing trained against a common paling fence. Is said to myself there is a lesson for me" That occurred about 40 years ago. Perhaps my notable South Yarra specimen may in like manner stir up some one. Those who are so disposed may visit intresting orangeries in the vicinity of Melbourne, and will be repaid for their trouble. They are, of course, possessed by the wealthy. My object is, however, as I said before, to popularise. I will next adduce and example of lemon growing by a professional—Mr. H. U. Cole, of Shorland Nursery, Upper Hawthorn. About three months ago I visited his establishment, and saw many excellent specimens of horticulture and pomology, but two lemon trees rivetted my attention. Plenty of space afforded—each occupied a somewhat rising ground—and so thick was the foliage that you could see neither stem nor branch from top to bottom. (I may be allowed to say that some magnificent loquats in the adjoining garden, his father's, Mr. T. C. Cole, were similarly trained, the surface roots protected from the sun.) From each of these trees upwards of 100 dozen lemons have frequently been gathered in a year. Now, 2,400 fruits from two trees, at retail price of 6d. each, represent £60. I know that I have had to pay 6d. when requiring the best fruit for an invalid; but, making a liberal allowance, the grower in this instance realised probably about £40, certainly not a bad revenue from two trees. And here let me—for others' benefit—relate a lamentable instance of my own ignorcane. Some years since, thinking to greatly improve my lemon tree, I set about to dig deeply all round it, and even under the branches, liberally manuring it also, my efforts being rewarded by a plentiful lack of foliage, &c. The tree was "fertile in its own disgrace." And no wonder. I was unconsciously sapping its very vitals. Discovering at last what all growers of the citrus ought to know at first—that the tree thrives by its surface roots, which must not be disturbed—I at once changed my treatment, and am happy to say that a more beautiful object of its kind than this much-abused plant I would not wish to see—rapidly growing and giving promise when fully recovered of bearing well. I now make a great skip to the banks of the Murray, merely remarking that a few years ago, when in Beechworth for a day or two, I greatly admired some robust specimens of orange trees in that town. And here let me say that I have the singular advantage of reading my paper before both amateurs and practical gardeners, who will, doubtless, supplement my crude assertions with their matured judgment. I confess to having had this mentally before me from the first, and shall consider myself exceedingly successful if I can by boring down, as it were, into the experimental depths of my audience, educe thence a flow of instruction that, carried through the channels of the press and otherwise, will benefit many. The scene then changes, and we have presumably reached Murray Downs, lat. 35deg. 15min. S., longitude not required. In casting about for materials for this paper I perceived hulling in the sea of Melbourne reminiscences a splendid exhibition of the citrus family, ticketed as grown by Mr. S. H. Officer, "of that ilk," and upon consideration I wrote to that gentleman, at Toorak, requesting a little information. It was courteously furnished, and I proceed to quote largely from it, being confident that you will coincide with me in thinking such quotations to be the most valuable part of my paper. Let Mr. Officer speak for himself, viz:—

"In 1865, in a very unfavourable position as far as both soil and exposure are concerned, I planted about 100 in all of orange, lemon, and citron plants, and the results in uantity, quality and size of fruit have far exceeded my expectations. When I commenced there was not a single tree growing in the place save one willow and a few half-dead English fruit trees. The place is in the middle of a large plain, with a southern aspect, and therefore fully exposed to frost, and had at the first no shelter of any sort. By planting red gum and willows in and near the edge of the swamp which formed one side of the orangery, in the course of a few years a pretty strong break against the violent storms of wind was formed. I carted a foot or more deep of the stiff clay soil from the bed of the dry swamp and mixed this well with the sparse loam of the natural ground, adding also manure and broken bones, and planting the trees in this, sheltered each one for two or three years from the frost of winter and the summer sun, and after that left them uncovered to grow alone. As the rainfall was only about 12in. or 14in. per annum, no fruit trees could live long without a plentiful addition of water artificially applied. To do this efficiently and economically I raised the necessary water from the Murray with wind and horse power and reticulated it in pipes throughout the garden. In about three years some of the orange trees commenced to bear, and all soon after, also the lemon and citron trees. On some of the first trees I have measured fruit (some years) nearly 16½in. in circumferencer with rather thick skins, but of the most delicious flavous and very juicy. These fine qualities I attribute not so much to the rich made soil as to the abundant supply of water the trees received. This is shown by the trees in some instances this year (1882) producing 'fozy' fruit, deficient in both size and quality, and becoming tasteless after being gathered a fortnight; and then I found that the gardener, from a false notion of his own, had neglected to water fully. With water in quantity up there we can produce almost any fruit, even gooseberries. Apples grow to perfection, and stand the hottest winds and sun without the slightest scorching. Raspberries, strawberries, peaches, apricots, plums, figs, and other fruit can scarcely be excelled. The lemon and citron trees have rewarded my attention, if possible, more bountifully than the orange. The former, at least, are more hardy, stand the frost better, and take root more readily than their companion oranges; and we can propagate them easily by layers. Those in the garden had the advantage of being all in much better soil than many of the orange trees, and when the watering was well attended to the quantity and quality of fruit was surprising. I have forgotten the measurement, but can truly say I never anywhere (and I have been in many parts of the world) saw finer or larger fruit. The citron is a most beautiful and ornamental tree, and bears an immense mass of fruit year after year without any injury to its growth, or impairing its vitality in any apparent degree. All the family are liable to the same disease which has destroyed so many in Sydney—a decay of the bark round the stem of the tree, just under the soil; but by taking this in time, and paring away all the diseased part, and binding it closely round with cloths, we have generally saved the tree,

though not a few have died. The scale blight requires unremitting attention, but late and more economical remedies now enable me to overcome this with ease."

Being desirous of learning, that I might make known the remedy, I again wrote to Mr. Officer, who replied thus:—

"Soft soap, 1lb (not less) to four gallons of water, and applied so hot that the syringe has to be held in a cloth, and used at a distance of a few feet. By the time the jets reach the tree the temperature has fallen sufficiently to not in any way injure. I have found this plain solution both here (Toorak) and at Murray Downs to be all we could desire. The trees may require a second dressing, if bad with the insect, but rarely so."

He adds—

"The soil and climate of the Murray, from at any rate, Echuca downwards, are admirably adapted for the growth of the citrus family, with the aid of artificial watering, energy, industry, and steadiness of purpose. From about 20 miles below that place, where the banks become low, and the rise and fall of the river is not more than 12 to 16 feet, to about 15 miles above Murray Downs, on both sides of the river, the Murray banks for a quarter of a mile inland, and as much further as pipes could be extended, might be made a perfect garden of Eden for productiveness of fruit."

In conclusion, I venture to assert, as fair inferences from the facts and illustrations adduced, that (1) wherever in all Victoria a supply of water can be secured, every suburban cottage, every farmer's homestead and selector's shanty should have at least two members of the citrus family attached to it, viz., the orange and the lemon; (2), carefully tended during the first three years, and not neglected afterwards, they will amply repay, by their hardy beauty and fertility—aye, and fragrance too—for neroli oil, one of the most delicious perfumes, is extracted from their blooms—all your trouble; and, meet companions of the vine and fig, will unite with them at once to banish the reproach of bare walls and unsightly surroundings, and to replenish the domestic board with their healthful juices and valuable conserves. Let us not forget, however, Mr. Officer's admonition as to "energy, industry, and steadiness of purpose." Nature resents your perfunctory, happy-go-lucky attentions. She yields her riches to those only who give her their hearts as well as their hands. Rightly wooed, she honours her suitor after no scanty fashion. *Note.*—It seems that good plants of the citrus family, about 3ft. high can be obtained from Parramatta at £5 per 100.—*Australasian.*

Trade of Borneo—Brunei.—The following is from the Report by Consul-General Leys on the trade and commerce of Brunei for the year 1881:—The return of exports shows a very decided increase in the values of all the jungle produce (bees-wax, birds'-nests, gutta-percha, and camphor, especially the last) exported during the past year; the amount of gutta-percha, however, although less than that exported in 1880, was greater than that exported during the five years preceding 1880. The greatest decrease occurs under the head of sago flour, the value of which export forms about half of the total value of the exports. The great decrease in the value of sago exported during the last two years is mainly due to a drought that occurred in 1878, followed by extensive jungle fires extending over many miles of country. This drought lasted six months, and was the most severe that has been experienced in this part of Borneo for many years. These fires increased the actual amount of sago brought to the market during 1879, as many of the palms that were not fully grown, but had been severely scorched or killed by the fires, were cut down, and the raw sago extracted before they began to rot. The quantity of sago brought to market during the last two years was also much influenced by the low prices sago commanded during that period. As before remarked, these figures only show the value of sago flour exported from the two factories in the city of Brunei, and not from the other two factories on the coast. The only other export of any importance is tapioca. Several hundred acres of it were planted by an enterprising Straits-born Chinaman in 1879, on a low hill two or three miles from the city of Brunei. The experiment has not proved a success. Much of the ground on which it was planted was so steep that the heavy rains kept constantly washing the soil from the roots: the soil itself is not rich, and the depredations by men and wild pigs on the roots which did grow well were very considerable; agricultural labour also is very scarce and dear in Brunei.—*London and China Express.*

Esparto Fibre for Paper-making.—A meeting of paper-makers and others interested in the paper trade was held on Tuesday afternoon at the Spread Eagle Hotel, Manchester, to hear a statement as to a movement for bringing an increased supply of esparto fibre into the market. Mr. W. Huntingdon (Darwen) presided. Dr. Matter (London) said the Franco-English Esparto Fibre Supply Company had been formed for the purpose of developing a concession by the Bey of Tunis to M. Duplessis of the exclusive right to collect and export esparto grass grown in the territories of Bouhedma, Majoura, Aicha, and Haldji. He had been to Bouhedma and satisfied himself that from that district alone 30,000 tons of esparto grass could be exported annually, and the labour necessary could be obtained on the spot. A tramway would be laid down to the nearest port and hydraulic presses erected, and the grass could be delivered in Liverpool for £3 18s. per ton, against £7 5s., the price of Sfax grass last year. A resolution was adopted to the effect that if the Company could do what it proposed it would have the support of the trade.—*Public Opinion.*

Tanning: Analyses of Barks.—The following analyses of samples of bark, leaves, &c., supposed to be useful to the tanners, has recently been furnished to the *British Trade Journal* by Mr. W. N. Evans, of the Tanners' Laboratory Taunton:—

	Tannic Acid. Per cent..
West Indies—	
Locust tree	10·02
Buttell tree	6·06
Guava tree	9·77
Pimento tree	19·70
Broadleaf tree	20·32
Trumpet tree	4·52
Red mangrove tree	27·13
Seaside grape tree	14·16
East Indies—	
Lepidospesuria tree	8·72
Wynaad bark	11.22
Vaingra bark	17·20
Spain—	
Jara plant	
Leaves	12·33
Bark of root	15·09
Dead leaves	11·35
Seed pods	9·50

As many of the above trees grow in this colony, the information as to these new tanning materials may be of service to the trade.—*Queenslander.*

Ploughs on the Saidapett Farm, Madras, by Mr. Robertson are thus noticed:—Great difficulty has been met in experimenting on the farm with single-handle ploughs made like the country plough. The farm ploughmen have, for years, used only the double-handle ploughs of the European pattern, which require far less exertion on the part of the ploughman, than country ploughs. The men most decidedly prefer the double-handle ploughs. A great deal of nonsense has been written regarding the supposed advantage of a single-handle plough, in its admitting, when at work, of the ploughman using one of his hands in twisting the tails of his cattle. The farm ploughmen plough a much larger area of land in a day than is usually ploughed elsewhere, yet, as has already been noticed, they work only double-handle ploughs, and never touch the tails of their cattle; indeed, any such reprehensible performance in tail-twisting, though apparently, in some quarters, deemed inseparable from ploughing with cattle, would lead to the immediate dismissal of the ploughman. Each ploughman uses a pair of reins, and carries on his plough a light whip, which he occasionally uses. Each man manages entirely his own plough and cattle; some of the men can make as straight a furrow as, is made in other countries. A new implement was constructed, which promises to be useful. It is a copy of one used largely in Germany. It consists of a strong iron beam, which has holes for the reception of coulters fitted with shares; these are broad and narrow for broad sharing, grubbing, or sub-soiling; and one of the coulters is fitted with a mould-bard, so that the implement may be used as a cultivator, a grubber, a sub-soiler, and as a plough. Attention is being given to this implement, in view to its further improvement and adaptation to the wants of this country.

GERMINATION OF SEEDS.—Some interesting results concerning the germination of seeds have been obtained by. Dr. Liebenberg, and published in the *Journal of the Vienna Academy of Sciences* (*Garden*, Dec. 2nd p. 480). He finds that many plants require the presence of lime in the soil during the germination process, and that the seedlings die if it is not present. On the other hand, there are some plants which germinate freely without it. The cinchona trees are known not to require lime, but the frequent failure in Jamaica to raise seedlings, may perhaps, be due to the soil not containing the other ingredients necessary to their healthy growth.—*Pharmaceutical Journal.*

CASSIA.—In a note read at the Linnean Society, by Mr. W. T. Thiselton Dyer "On the Origin of *Cassia lignea*," he remarks that the want of exact evidence as to the botanical source of this spice is now cleared up. Mr. C. Ford, Superintendent of the Botanical Department at Hong Kong, has made an expedition to the districts in which the cassia tree is cultivated, and has brought back herbarium specimens in flower, which prove to be those of *Cinnamomum Cassia*. So far as Mr. Ford could ascertain, cassia buds and leaves as well as barks are obtained from this tree only. The leaves are sent to Canton for the distillation of oil of cassia, and the buds are gathered when about one-eighth grown. The thick bark, so much valued by the Chinese, is obtained from trees reserved for seed bearing, when such can conveniently be spared for the purpose.—*Ibid.*

FLOWERING OF PLANTS.—It is not unusual to see violets and primroses and other spring flowers blossoming in the mild weather of late autumn, especially if they have been prevented from flowering by having been transplanted at the period of flowering. From some interesting facts stated by Dr. Brandis in the *Indian Forester* for July, 1882 (communicated by Mr. W. T. Thiselton Dyer to *Nature*, November 23rd 1882), it would appear that similarity of season has more to do than the time of year with the time of flowering. Dr. Brandis observed that from 1845 to 1850, *Acacia dealbata*, one of the Australian wattle trees, flowered in India in October; in 1860, it was observed to flower in September; in 1870, in August; in 1878, in July; and in 1882, in June. In Australia the tree flowers in October, which is the spring month there. In Ootacamund, the corresponding month is June. The tree has thus gradually worked back its time of flowering from October to June, from Indian autumn to Indian spring, during a period of forty years *Acacia decurrens*, in the same way, appears to have flowered, during May to July, at Kew, in 1790, but now blossoms in February.—*Ibid.*

MEDICINAL PLANTS.—At a meeting of the Linnean Society, Mr. W. E. Armit, of Queensland, contributed a paper on "The Native Medicinal Plants of North-West Australia" Among these he enumerated *Erythræa australis*, used as a tonic in febrile compliants; *Careya arborea*, a myrtaceous plant, the leaves of which are used as an application to ulcers; *Grewia polygama*, a tiliaceous plant, said by the author to be very useful in dysentery, he having "never known it to fail in any case, however serious," *Petalostigma quadriloculare*, a euphorbiaceous plant, the bark of which is used as a tonic in fevers in does of 10 grs. three times a day; *Datura australis* and *Euphorbia pilulifera*, remedies for asthma. Of the two last, the former is said to be fatal to horses and cattle, the latter has recently been introduced into this country, and appears to valuable as a remedy for bronchitis as well as asthma. Dr. A. F. Currier, of New York, has published in the *American Journal of Medical Sciences* (October, 1882) an article on the use of *Eucalyptus Globulus* (*Med. Times and Gaz.* Dec. 2nd, p. 666.) The oil is said to diminish the action of the heart and the blood pressure, and to act as a stimulant, astringent and antiseptic on mucous membranes. It is also said to destroy entirely the unpleasant smell of iodoform. Dr. Currier speaks highly of its use as a disinfectant and antiseptic in chronic ovaritis and tumours of the breast in removing the fœtor of the discharges and relieving the pain and discomfort.—*Ibid.*

CHEMISTRY OF VEGETATION.—Several valuable memoirs have recently been presented to the Academy of Sciences upon points connected with the chemistry of vegetation. M. Leplay (*Comptes Rendus*, xcv., 1133) has given the conclusions he has drawn from the analysis of the different organs of maize at three different periods of its vegetation. He has found that at the end of the first period of vegetation (1st July) potash and lime are present in all parts of growing maize, in the soluble state in combination with vegetable acids in the juices, and also in the insoluble state in the tissues. From this time however, no more potash appears to be taken up from the soil; but that already present in the plant in soluable organic combination undergoes an extraordinary migration from one part of the plant to another During the second period the growing ear is supplied with potash entirely at the expense of the stalks, which lose as much as 39 per cent. of the quantity present in them at the end of the first period; but in the third period the porportion of this base in the stalks is restored to the extent of about 25 per cent., the reserve drawn upon now having previously been stored up in the leaves. The quantity of potash in the roots is not affected or only very slightly diminished during these movements. On the other hand whilst the total quantity of potash in the plant remains stationary, the amount of lime in organic combination in the different parts of it is increased during the second and third periods (July 1st to September 1st) by about 140 per cent., the first augmentation taking place in the stalks, from whence as the plant approaches maturity it passes in considerable quantity into the ear and especially into the seeds. During the formation of the reproductive organ the potash in organic combination with the tissues is gradually diminished and disappears entirely from the stalks, being replaced by lime. The vegetable acids combined with the potash and lime are considered to have their origin in the carbonic acid taken up by the plant from the soil in the form of carbonate or dissolved in water. According to M. Leplay *Comptes Rendus*, xcv., p. 895) this transformation is effected by (1) reduction of carbonic acid or elimination of oxygen; (2) condensation or assimilation of carbon; (3) assimilation of the elements of water in the same proportions as they exist in water. Equations representing the manner in which these changes are supposed to take place are given in the paper.

Another memoir, by M. Leplay (*Comptes Rendus*, Nov. 27th) throws some light on the relations between the presence of starch and sugar in plants. He found that sugar occurs in the leaves and accumulates in the stem until the moment of the formation of starch in the seeds. It then passes first into the inflorescence to support it, and subsequently into the seeds themselves, where it is replaced by starch. The function of the sugar would appear, therefore to, be that of furnishing the seeds with the elements of starch.—*Ibid.*

CINCHONA BARK.—The Accounts relating to Trade and Navigation of the United Kingdom just issued, show that the "Peruvian bark" imported during the year 1882 weighed 138,763 cwts., and was of the estimated value of £1,781,482, whilst there was exported only 80,014 cwts., valued at £903,332. This would leave a good margin for the quinine manufacturers.—*Pharmaceutical Journal.*

CEYLON FIBRES.

The receipt of Dr. Trimen's letter on page 886, recalls our omission to deal with several samples and a good deal of information placed at our disposal in reference to local fibre-yielding plants of marketable value. This we must do in an early issue. Meantime we may say that Mr. C. Shand, who made experiments in the preparation of fibre from the *Sanseviera zeylanica*, produced a sample which was valued at £25 per ton; but he came to the conclusion that as the yield of fibre was only equal to two per cent, there was not sufficient margin for profit unless some very cheap means of separation were made available. It is a question however, as Dr. Trimen points out, whether the preparation of fibre from this plant, could not be made a native industry of some importance to people who have more time on their hands than they can utilize profitably. The revenue officers of Government should interest themselves in the matter.

FARMYARD AND ARTIFICIAL MANURES.

Of the value of farmyard manure, especially if composed of the droppings of animals fed on highly nitrogenous substances and well protected from the weather, there never was any doubt, we suppose, amongst either merely practical or scientific farmers. The Rothamstead experiments of Sir J. B. Lawes, indeed, resulted in proving that the beneficial effects of a liberal application of good farmyard dung could be traced up to a period of nearly a quarter of a century after the date of application. So much has farmyard manure been valued in English farming that the reserve of a portion of each farm for grazing purposes and the growth of hay has a recognized practice in orthodox agriculture as well as the cultivation of turnips and other roots. The feeding and the sale of stock, in truth, received in many cases as much attention as the growth of corn crops; for in a meat-eating country like England, and so long as cattle-disease was absent, the feeding and sale of surplus stock paid well. So much importance, indeed, was attached to farmyard manure by proprietors of land, that it was, and we suppose is, an almost invariable condition in leases to tenants that all straw is to be eaten or used on the farm: none sold away from it. Farmers suffered specially when epizootics appeared; and the chronic objection to farmyard manure was its enormous bulk and the proportionate cost of application. Here, in Ceylon, all the difficulties were aggravated. The mere growth of guinea or swamp grass was very expensive; oil-cake and imported gram, paddy and cotton seed were still more costly; cattle were specially liable to disease, and even for fattened cattle and pigs the market was neither steady nor remunerative. In 1879, therefore, when, with a great flourish of trumpets, Mr. Crookes, F. R. S., introduced to English readers the plausible and seductive work of the Frenchman, M. Georges Ville, we, amongst tens of thousands of others, were taken captive by statements which appeared to be the legitimate outcome of carefully conducted experiments. It seemed beyond doubt, for instance, that certain plants derived most of their nitrogen directly from the air. But Sir J. B. Lawes, who has unsparingly unmasked the sophistries of one who is now declared to be neither a practical farmer nor a scientific man, has shewn that M. Ville's conclusions were arrived at by taking into account only the nitrogen in the manure applied to the soil with reference to a particular crop, while the nitrogen in the arable soil itself, from 10,000 to 12,000 lb. per acre, was entirely ignored! This is but a specimen of the fallacies which, according to a notice in the *Field* of Sir J. B. Lawes' articles in the *Agricultural Gazette*, pervade the whole book, and readers who have seen our elaborate review of M. Ville's work, with a summary of his conclusions in favour of artificial manures *versus* pasturage reserving and stock feeding for farmyard dung, will correct their impressions accordingly. The sober view of the matter is that farmers in Europe should continue to use farmyard manure and good artificial manures as well, taking special care that the farm manure is rich in fertilizing matter as the result of the food supplied to the cattle, and that it is reduced to as portable a form as possible. For us, in Ceylon, the discussion is not of much practical importance at present. When planters are able again to resort to manuring, most of them will only be able to add pulp and prunings and ravine stuff to good artificial manures. In a few cases the keeping of cattle may pay even now, there being a near market for surplus stock, and the day *may* come when stock-keeping and manuring estates with cattle dung (the best and most lasting manure of all) will pay. Meantime, it is well we should know and recognize the truth, as stated by so reliable an authority as Sir J. B. Lawes. We copy the article from the *Field*:—

ARTIFICIAL MANURES.

As far back as 1879 a work on Artificial Manures appeared in this country, written by a French chemist, M. Georges Ville, and translated and edited by Mr. Crookes, F. R. S. Few works on agricultural matters have caused more interest. The writer gave his opinions with so much confidence—quoting experiments in proof of the conclusions he had arrived at—that the public were very much carried away, and disposed to take M. Ville at his own valuation. The work was favourably and largely noticed, and we think that *The Field* amongst other papers, called attention to the remarkable results said to have been obtained by the use of artificials, and also to the statements as to the power of certain plants to obtain supplies of nitrogen direct from the atmosphere.

Quite recently Sir J. B. Lawes has published in the pages of the *Agricultural Gazette* a series of seven articles which will be found in the numbers from January 1st 1883, in which he subjects M. Ville's statements to a critical examination, and exposes their utter unreliability. The farming public, who are interested in this question, are much beholden to Sir James B. Lawes for having detected these fallacies, which as their principal object was to discredit farmyard manure and to exalt the virtues of artificials, and especially of certain receipts which appear at the end of the book, might, if accepted by English farmers, have led to great losses.

Artificial manures, suitable to the particular soils and crops, are valuable supplements to farmyard manure. But this, as containing all the materials required in plant food, though perhaps not always in the exact proportions most necessary, and being made, as a rule, at much less cost than what we pay for artificials, should be for nine-tenths of us our main resource. Instead of our being led away by a will-o-the-wisp in the form of patent manure, and so induced to continue the wretchedly wasteful methods of manufacture which still too frequently prevail, we should be told how we may improve our practice, and how, by making and keeping our manure under cover, we may secure a concentrated and portable material, which will if we only have enough of it, render us to some extent independent of artificials. The more we can replace the outlay now made in artificial manures, by outlay in feeding materials which enrich the droppings of animals eating them, the more profitable will be our operations, be-

cause we shall get back much of our outlay in the animals, and we shall have a much more permanent manure; for, as the reviewer points out:

If there is one fact more than another upon which all practical farmers in Great Britain are absolutely agreed it is that of the lasting properties of farmyard dung as compared with artificial manures; and I may add that the general result of the Rothamstead experiements has not only been to confirm the experience of practice but even to extend the operation of the dung to a far longer period, than that generally assigned to it.

This sentence was *apropos* of a statement to the effect that the idea that the farmyard manure in an experiment of a M. Consard had not been exhausted in one year, whereas the chemical manure had been exhausted, was "contrary to all the known facts." It may be as well to give the quotation from the preface to the French edition referring to this same experiment, as an illustration of the delightfully vague way in which matters whose value depends upon exactness, are treated:

M. Ponsard, president of the Agricultural Chamber of D'Ourcy, in Champagne, made two parallel experiments on a piece of waste land in one of the most barren districts of a proverbially barren portion of that province. He manured one half of the ground with about 32 tons of farmyard manure per acre, and the other with about half a ton of chemical manure per acre. With the farm manure he obtained about 14 bushels of wheat, whereas with the chemical manure the land yielded about 36 bushels, there being a loss of £19 in the former case, and a gain of £17 in the latter.

If the figures as to profit indicate the general accuracy of the whole, we may pass over M. Ponsard's experiments as absolutely unreliable, seeing that, whilst M. Ville tells us that the cost of growing wheat (which, under the present system of agriculture, is 5s 6d a bushel) may be reduced to 3s 9d, he yet would have us believe that thirty-six bushels of wheat realised a profit of £17, equal to 9s a bushel; and this is of course, supposing no value for the land, and no expense in its cultivation.

As regards the important question as to the sources of the nitrogen of plants, M. Ville's statements as to the power of plants to derive a portion of their supplies directly from the air blown to the winds by a mass of facts, the result of actual experiments. M. Ville states that nitrogen is assimilated by plants in three different forms, viz., as ammonia, as the nitrate of some base, and as nitrogen gas; and that it has been ascertained that "crops always contain more nitrogen than the manure supplied to them, and this excess is derived not from the soil, but from the air." Such a positive statement is proved by Sir J. B. Lawes to be absolutely erroneous in every instance. Wheat most nearly, of all our cultivated crops, accounts for the nitrogen supplied in manure. In every other instance where excess of nitrogen above that contained in the manure is said to be derived from the atmosphere, the very opposite is the fact—the manure contains more nitrogen than appears in the crop, and a considerable loss occurs. In the analysis of the soil in which his experiments were carried out, though *made with the greatest* care, no mention is made of nitrogen, but he refers to it as similar to that of Rothamsted as to the nitrogenous matter. Sir J. B. Lawes states that within reach of agricultural crops, the arable soil contains from 10,000 lb to 12,000 lb of nitrogen per acre; but, apparently M. Ville leaves this out of calculation altogether; and, because he finds more nitrogen in certain crops than was supplied in the manure, jumps to the conclusion that the balance was derived directly from the air. In the case of wheat—which, as has been shown, makes the best use of the nitrogen supplied—it is shown by the reviewer that 1 cwt. of nitrate of soda furnishes 17 lb or 18 lb of nitrogen, and that if every particle were taken up this would suffice for 11 bushels of extra wheat, and he thinks farmers would be satisfied with 6 bushels on an average; and that even in 1863, the year of maximum produce at Rothamsted, the amount of nitrogen in the increase of the experimental crop was considerably less than that supplied in the manure.

As regards beetroot, M. Ville's statement that there is an excess of 114½ lb per acre over that furnished by manure, which is derived from the atmosphere, appears, to us wide of the mark; and this is actually proved from the experiments he quotes. Thus, certain manures without nitrogen resulted in a yield of 14 tons 14 cwt. of roots per acre. By adding to the minerals sufficient sulphate of ammonia to supply the respective amounts of 176 lb, 220 lb, and 264 lb of nitrogen per acre, a respective increase was obtained of 4 tons 6 cwt., 5 tons 14 cwt. and 9 tons 2 cwt. per acre, Now, as the highest increase could not have contained more than 72 lb. of nitrogen per acre, and the smallest application of that substance was 176 lb. it is evident that, instead of a gain, there is an enormous loss of nitrogen. Another most remarkable statement is that the *profit* on an application equal to 12 cwt. of sulphate of ammonia, which caused an increase of 9 tons 2 cwt. of beets. was £9 2s 6d. Numermous other gross blunders, inaccuracies, and contradictions, are pointed out. Thus, in one place we are told of experiments in which artificial manures proved more permanent, and in another lecture that farmyard dung, "owing to its nature and its bulk, necessarily acts very slowly . . . and becomes the equivalent of a large amount of acquired riches.

Perhaps the most amusing part of M. Ville's book—which must be really considered more in the light of a romance of agricultural science than a work dealing in facts—is that in which he criticises Boussingault's farming operations and balance sheets. Discovering a mare's nest as respects the value put on the manure, he makes out balance sheet No. 2, which, with the correction as to the value of the manure turns Boussingault's modest profits at Bechelbronn, shown in his balance sheet, into a loss. Next, by the use of certain artificial manures, crops are to be trebled, and the balance put on the right side to the tune of £525. 11s. 2d. Thus is developed balance sheet No. 3; and in a fourth balance sheet the profits are actually increased to £635, 4s. 10d.

Sir J. B. Lawes points out many other errors which our limits will not allow us to recognise. Enough has been advanced to act as a warning to our readers not to blindly follow the advice of one who, however well-intentioned, is not a farmer, nor a scientific man, but is evidently profoundly ignorant of agricultural practice. The season is coming on when artificial manures will be in use. They are, when composed of genuine ingredients suitable to the crops and the soil, valuable as additions to the manurial resources of the farm; but, whilst we venture money in such aids, let us take care that we get as much as we possibly can form our home materials.

REPORT OF THE BOTANICAL GARDEN OF JAMAICA FOR THE YEAR ENDED 30TH SEPTEMBER 1882.

It is not one Garden but at least a dozen which Mr. Morris reports on in the Supplement to the *Jamaica Gazette* of February 22nd, of which an "early copy" reached us by the French mail. We have read this document of 19 folio pages with much interest, and we shall draw upon it for a great deal of valuable information bearing on similar enterprize here. Jamaica suffers now as it ever has done from occasionally unfavourable seasons and from a cause of swift and terrible destruction of which we in Ceylon know nothing: hurricane. The island has not yet recovered from the last storm which swept over it, and there has been a trying reaction from floods to dronght. On the other hand the West Indian island possesses fertile soil of volcanic origin, and for all the fruit it can possibly grow, in the shape of coconuts, pineapples, oranges, mangoes, bananas, &c., there is a practically illimitable market close at hand amongst the fifty-five millions who inhabit the United States, a large proportion of them eminently fruit-eaters. Neither in soil nor in contiguity of markets, is Ceylon so favoured, although we cannot doubt that, as steamer intercourse increases and refrigerating apparatus are perfected and cheapened, there will be a large and increasing demand for tropical fruits and for vegetables, not only to supply passenger ships but to supply the Presid-

ency and principal towns of India and to some extent Covent Garden in London and the East Market in Melbourne. Our one great advantage lies in the direction of a plentiful and reliable labour supply. The negroes of Jamaica have ever been given to a semi-savage and thriftless system of squatting and growing almost exclusively ground provisions, and now those of them inclined to work are going off in shoals to Panama, to give their labour and in too many cases their lives under the incitement of wages equal to $1, or 4s 2d, per diem. Still progress has been made, and those who may be contemplating the establishment of extensive and systematically managed fruit orchards near Colombo will be interested in the details of the Jamaica fruit trade which Mr. Morris affords. Reserving a special notice for those portions of the report which deal with the very successful cinchona enterprize, we deal today with the fruits which are exported to America. And first, beyond compare, in importance, is the prolific combination of starch and sugar which we in Ceylon call the plantain, but which in the West Indies and all over the western world and also in Australia is known as the banana. An authority in whom, from his long experience and shrewd observing habits, we have much confidence has condemned the plantain as a shade plant for cacao (supposing shade were needed) because of the soil-exhausting nature of the plantain itself, orchards of the plant needing to be manured in order to save them from a condition which in the West Indies is indicated by the significant word "ruinate." The difference in favour of the soil in Jamaica is shown by the fact that Mr. Morris all through his reports takes it for granted that the growth of plantain as a shade plant will not deprive the main culture of cacao of any material portion of the fertile elements it needs. At the very commencement, Mr. Morris writes of cacao "which, combined with that of bananas, promises to be an important industry"; and when he comes to deal specially with the banana enterprize he writes :—

BANANAS.—This is the leading fruit interest in the island, and it is being prosecuted with energy and success by both European and negro settlers. As a nurse industry preparatory to that of cacao, banana cultivation deserves every encouragement.

It is to be hoped that no land placed under banana cultivation, which is, of necessity, according to the strength and character of the soil, of a more or less temporary character, will be allowed to fall into ruinate. Every banana plant should be utilized as a nurse for a cacao plant and thus when the banana fails, the cacao will take its place, to remain as a permanent cultivation, and a source of continued wealth to the colony.

Where bananas obtain good prices, as in Jamaica, it is no exaggeration to say that a cacao estate can be established here under more favourable conditions than in any other British possession.

The export of the fruit had risen from 163,000 bunches valued at £16,000 in 1877 to 887 000 bunches valued at £88,737 in 1882. The valuation seems to be at the rate of £1 for ten bunches. We have counted 250 separate fruits on a bunch, and we have no doubt 300 has been reached and exceeded. But, taking 100 fruits as an average, we get 887 millions of fruits exported in 1882, of which, allowing for the perishable nature of the fruits, some 750 millions must have gone into consumption in the United States. The plantain is, undoubtedly, not only a palatable but a wholesome and nutritious fruit, and, according to Humboldt, yielding a return of nutritious matter per acre, fortyfold more than wheat. Plantains split and dried in the sun or in an oven closely resemble figs, to which many prefer them. The stems, which, like those of the raspberry, yield only one crop of fruit, had better be left on the ground as manure. Mr. Routledge the papermaker, has finally pronounced against them as fibre plants, the proportion of fibre to watery matter being so minute. The next fruit on the list is the orange, and of this fruit the export has increased from 8,238,000 valued at £5,767 in 1877 to 35½ millions in 1882 valued at £33,684. The export of pineapples is still limited, the figures for 1882 being 8,887 dozens valued at £1,111; but Mr. Morris writes :—

Continued attention is being given to the cultivation of pine-apples in the neighbourhood of Kingston and generally in dry sandy districts within easy reach of shipping facilities.

In order to assist this industry, I have lately obtained through the Royal Gardens, Kew, a selection of all the best pines under cultivation in England such as Lord Carrington, Smooth Cayenne, Lady Beatrice, etc., etc., which, with those already in the island, will place cultivators in possession of the finest strains for size and colour obtainable anywhere.

I have also, by the kindness of Mr, Anderson, obtained plants of the "Scarlet" and "Cuban" pines from the Bahamas, which obtain so much favour in the New York market.

We have no doubt Dr. Trimen will show himself willing to secure equal advantages for Ceylon, where pineapple cultivation ought to be profitable with reference to fibres as well as fruits. The export of mangoes from Jamaica is also in its early stage, the figures for 1882 being 150,671 fruits valued at £145. Mr. Morris remarks :—

The East Indian mangoes are being gradually distributed throughout the island, which, as they possess better keeping qualities than the celebrated No. 11 mango of Jamaica, should receive greater attention from those who grow this fruit for shipment. The export value of mangoes is steadily increasing, and, before long, if properly selected and packed, they will no doubt form an important article of commerce between this island and America.

In consequence of the drought the export of coconuts had decreased from 6,315,000 in 1880 to 2,560,000 in 1881. The total value of fruit exports in 1882 was £135,000, and it is impossible to predict the dimensions to which it may grow. We do not see why Ceylon also should not besides supplying local and passenger steamer demand, have a profitable export trade in table fruits.

HOW THE CHINESE MANUFACTURE "LIE TEA"

is revealed in a letter to the *Argus* from Mr. Bainbridge, the Assam planter and tea expert who, at Mr. J. L. Moody's request, reported on the rubbishy Chinese teas *recently* imported into Melbourne. We quote as follows :—

These teas are of a very inferior description, and are evidently mixed up with various foreign substances, which could not have been introduced in the ordinary process of manufacture in a properly managed tea factory. It is quite clear to me, as an experienced tea maker of 22 years' standing, that the samples are made up by an admixture of fair tea with old leaf, picked up from the ground, and infused leaf, which has been recoloured and renewed by steeping in a strong decoction of prunings mixed with some kind of starch or gum, to set the colour. On carefully separating and examining the infused leaf I found some which it is quite evident does not belong to any known variety of the tea plant, and there is also an undue proportion of stalk, and much dust and rubbish.

The factory in which these teas were manufactured must have been of the most filthy description, or the

rotten leaf and large quantity of rubbish mixed up with the teas must have been purposely introduced to increase weight and bulk.

When in Calcutta I saw some very similar samples tested by the leading firm of brokers and tea tasters there, and their report was as follows :—

"A small proportion of fairly made and fermented leaf, mixed with old infused and re-coloured leaf, dirt, dust, and rubbish ; valuation nil. These teas are quite unfit for consumption here."

Lots 6, 7, 30, 33, 53, 54 (pekoes) appear better, having a considerable quantity of oolong pekoe leaf mixed up with a smaller proportion of rotten coloured leaf, rubbish, &c. The unpleasant flavour is somewhat disguised by the large proportion of scented leaf intermixed. The improvement is, however, more in appearance than substance, as these teas, I find on examination, have an extreme proportion of stalks and dust, and are mixed with nodules of gum, rubbish, colouring matter, and other impurities.

As it may interest you to know the system usually adopted by the Chinese for colouring exhausted black-leaf teas, stalks, &c., I subjoin a short memo. of the method taught by the head Chinese tea-maker employed in the Assam Company some years ago :—

'A quantity of the old branches and useless leaves are collected from the bottom of the tea plants and pounded into a pulp in a rice-pounder or mortar, then tied up in a cloth and put in a hole in the ground to ferment for a few hours. When sufficiently fermented the pulp is placed in a large tea-pan, and boiling water poured on it. It is then allowed to boil until two-thirds of the water have evaporated. Then liquor is strained off, a proportion of gum and colouring mixed and the exhausted leaves and stalks steeped in it as long as considered necessary. The renewed tea is then partly dried, lightly rolled, and finished in the sun or on heated plates."

TRINIDAD BOTANIC GARDENS:

Tonga-bean ; Cola-nut ; Ceara' Rubber.

A report by Mr. Prestoe, Government Botanist of Trinidad, was published in the Trinidad Royal Gazette of November 1882. Under the heading Tonga-bean Mr. Prestoe says :—"There are large examples of this valuable tree in the Botanic Gardens, which afford evidence of the habit of growth of the tree and its requirements under the usual conditions of soil and climate here, and which in some districts appear to be exactly similar to those of the Tonga-bean districts of Venezuela. In the face of the commercial value of the Tonga-bean arising from a widespread and ever-increasing appreciation of its use in Europe and United States, as a flavouring in articles of enormous consumption which come under the head of indispensable luxuries as well as the more necessary food product—cacao. The price has already reached $2 per lb. Its cultivation in this Colony may be regarded as of the highest prospective importance and value ; the more so as the tree will thrive in land altogether too poor for cacao or sugar, and the forming of plantations (as with cacao) would have the great attendant advantage of maintaining the climatic and other conditions of characteristic of full afforestation (without its attendant drawback of malaria) so important in tropical agriculture, on land which once cleared is very liable to lapse into useless "blush," or "jungle overborne with malaria." Regarding the cola-nut Mr. Prestoe says : —"As may be expected, the price of the article has lately taken a sudden rise, and there is active enquiry from tropical agriculturists as to the characteristics of the tree bearing the Cola-nut and its prospective value as a subject for cultivation. As such it may be regarded only second in importance to the Tonga-bean. The general character of the tree is that of a strong growing cacao tree attaining the height of 30 or 40 feet with proportionate spread, and beginning to bear about the same age. Unlike the cacao as to requirements, however, it flourishes in comparatively poor soil and in exposed situations. The Cola-nut tree has been long grown in these Gardens, the original tree being now sixty inches girth, and from young trees put out during the last few years a very good idea of the disposition and habit of the tree as well as its requirements may be gained by those desirous of attempting its culture. The young plants progress satisfactorily without shade, if planted in moderately good soil, but in poor soil or dry situations, the usual shade afforded by plantain cultivation is advantageous or even necessary. The cultivation of the Cola-nut tree will therefore be of the simplest possible character. No particular as to soil, bearing full exposure, growing quickly from the large seed, the only care required will consist of suppressing native bushes of more rapid growth than it, and when matured and fruiting, to clean off the surface growth to facilitate the collecting of the seeds as they fall on the ground. Briefly, it will be a cultivation of a similar character but of much less cost than that of cacao, and suitable for land that may too dry or poor and exposed for that valuable cultivation. The process of planting up land abandoned as too poor for provision or other cultivation, or indeed any 'rastr'o' land would be the same as recommended for the Ceara-rubber tree ; only, the Cola-nut would not thrive in such a poor condition of soil as that tree." As to vanilla we read:—"The value of the produce of Vanilla from a few square yards, is so considerable that the rental of any house may be realised by Vanilla culture in the court yard, provided there be means for 1° maintaining a chequered shade or a diminished sunlight—to one third of that it usually is : 2° a few hard-wood posts and bamboo laths for horizontal trellises, and such vegetable matter or rubbish as is usually met with in yard or street—including, specially, horse droppings ; the trellising being of course for support, and the rubbish—mixed with the surface soil—being the compost for the nourishment of the roots, and through them the sustenance of the plant." Of Ceará rubber Mr. Prestoe writes:—"This rubber yielding plant, which is really only a gigantic form of Cassada, is specially adapted for cultivation in dry gravelly hill-sides. It has enormous power of root development and penetration, growing luxuriantly during the wet months, and becoming dormant and leafless in the dry season when the milk-sap is of great density. It thus shows its adaptability for poor soil and arid situations ; indeed the production of a satisfactory 'rubber' very largely depends on these conditions, for with trees in the gardens on moderately good and moist soil, under rapid growth as occurs in the wet season, the sap is watery and shows scarcely a trace of rubber globules. The cultivation of this tree is therefore a prospectively valuable one for the poor gravelly soils of the northwestern hill slopes. No preparation of the ground will be necessary beyond the reduction of useless and encumbering vine or bush growth : such trees as may be useful as timber or otherwise being left as shelter against the squalls of the wet season—the Ceara trees being somewhat heavy headed and brittle when in full growth. The young Ceara trees can then be planted—by labourers using ordinary grubbing hoes—singly wherever a space of 12 feet occurs among the indigenous trees left."

TIMBER FOR TEA BOXES.

One of the great benefits which railway extension, when completed, will confer on the rising tea industry of Ceylon, will be that of placing suitable timber, cheap while sufficiently durable, at the disposal of planters. Boxes of proper sizes can be transported in shooks, the parts so prepared that only putting together, hooping and nailing will be required. An establishment purchasing, seasoning and working up large quantities of cheap timber ought, it appears to us, even now to be able to supply boxes in shooks, which after bearing railway, cart and cooly carriage, would be cheaper than those made on estates by ordinary carpenter. In any case such boxes ought to be less liable to warp and so better suited to be easily and rapidly put together. Premising that some estates may be entirely destitute of timber, the whole question in the case of properties possessed of reserves must be one of cost: the fact being kept in mind that the market value of reserve timber ought to be approximately calculated. Wishing to have reliable data for comparison between estate-made boxes and those obtainable in Colombo, we have been making personal enquiries. In one case we found that *hal* and *mango* timbers were employed. Against the latter there is a good deal of prejudice owing to the supposed acrid quality of its juices, while *hal*, unless very carefully seasoned, would also be objectionable. The price quoted for an 80 lb. box was R1·80, with 5 per cent discount for a quantity. At another establishment we were shewn some well-seasoned *lunumedilla* timber which in appearance and texture seemed all that could be desired. Our only fear was that this really nice-looking timber was open to the same objection as the white and red cedars of India, that of being too good for the purpose. For it is not part of the function of the tea planter in India or Ceylon to supply the buyer of his tea with timber which can be advantageously utilized in England, unless he is certain of a price being bid high in proportion to the value of the timber and its cost to himself. If the boxes are made of well-seasoned timber, free from corrosive juice or offensive odour, not liable to attacks of dry-rot or insects, and able for a period of four months or so to resist exposure and knocking about, that is all which can be desiderated. The price quoted for an 80 lb. box of this really superior timber was R2·12, thirty-two cents, or nearly one-third of a rupee, dearer than the previous quotation. We cannot help hoping, however, that *lunumedilla* can ultimately be obtained at prices which will lead to its utilization for tea boxes. It grows rapidly to a great height and sends out so few horizontal branches that a very large number of trees could be grown on an acre of land. As the tree is said to be fit for timber purposes in its tenth year, it seems obvious that plantations of this fast-growing timber tree ought to pay well, by-and bye. Mr. W. Ferguson, with all his study of trees and their properties, is of opinion that of all the timber trees of Ceylon this is the best suited for the manufacture of tea boxes; but it is so useful for many purposes especially of boat-building and house construction (it makes beautiful ceilings) that we fear it is too expensive to be converted into tea boxes. As there is not much spare capital in the island and few persons who can afford to wait ten years even for a large return for their money, we commend the cultivation of this tree emphatically to the attention of the Forest Officers of Ceylon. The tree is especially a free seeder, so that hundreds of bushels of the seeds could be obtained at once. An allied tree, what in Ceylon we call popularly "the Persian lilac" (from its sweet-smelling lilac-like blossoms), has the same property of producing a large crop of seeds. We saw a specimen in Mr. James Henty's grounds at Kew, a suburb of Melbourne, and found that it was known in Australia as the "white cedar." We have never heard of its attaining the dimensions of a timber tree in Ceylon, but it ought to be more prized than it is as an ornamental dwarf-tree. Mr. Brace, who wrote an essay on tea cultivation which was published at the *Observer* office, gave a list of a dozen and-a-half timbers which he knew or supposed would be suitable, and noticed the *lunu-medilla* thus:—"MELIA COMPOSITA. Probably an excellent wood for this purpose. Beddome remarks:—'It is common in Ceylon and is known by the native name of *Lunu-middela* and Mr. W. Ferguson of the island says the timber is very light and cedar-like and in use for outriggers of boats and ceilings, and that it is said white ants will not attack it. This probably might take the place of our cedars, not only for boxes but for most of the items of furniture needed on an estate.'" Mr. W. Ferguson now writes:—

Hal is so inferior and so full of resin that it is only used for *coffins*. *Mango* wood is considered an inferior wood, but has been a good deal used for coffee casks.

The *lunu-midella* is no doubt about the best tree and timber for tea boxes in every respect in Ceylon. It is of very rapid growth, is still an abundant tree in the island, easily procurable, being floated down the rivers. It is used for the outriggers of Ceylon canoes; for kattumarams; is the best Ceylon wood for ceilings, because it has a slight look of mahogany and can be varnished or polished and is said not to be attacked by white ants; is very light but not strong, seasons very rapidly. It was described under several botanical names and generally as the *Melia composita* of Willdenow, but Mr. P. Hiern, who has worked out this order in Flora Brit. Ind. I, p. 545, restores its first or oldest name, *Melia dubia*, Cavanilles, and gives the following synonyms for it:—M. superba, Rox., M. robusta, Rox., M. australasica, Adr. Juss., M. æthiopica, Welw., M. Bombolo, Welw.,—and M. argentea, Hb. Ham I feel sure that it is also the Auletæa Javanica. Gaert. I. 277, t. 58, f. 2.

Seeds about the size of an olive, and very like them, can be had in abundance in their season. Tree very high, leaves tripinnate, very large, on tops of branches, not a good shade tree, because it is quite leafless at times.

I saw an advertisement in the *Observer* from the Madras Railway or Harbour Department some months ago, calling for tenders for a supply of this wood, as *Malay Tambu*, if I recollect aright.

Mr. W. Ferguson and others will, however, like ourselves, have to review their opinions in regard to *hal*, in the presence of a specimen box of this wood sent to us by the Manager of the Ceylon Company Limited. This Company has had its experience of bad as well as good woods, and the final conclusion is in favour of good, well-seasoned *hal* for tea boxes. This was intimated to us in answer to a letter of enquiry whether materials for tea boxes procured and prepared in quantity could not be sold at a price cheaper than the cost of boxes in many cases made on estates. Copy of a circular was sent to us, in which, we were told, we should find our suggestions anticipated. In this circular, amongst information in regard to the leading requisites for packing tea, we find the following:—

TEA CHESTS.—The Company have a large stock of thoroughly seasoned Hal wood cut up for chests, only requiring to be put together.—The chests are dovetailed, and their outside measurement is 24 in. by 19 by 19 in. so that ten chests make exactly 1 ton of 50 feet cubic measurement.

They hold 85 lb. Pekoe Souchong.
90 lb. pekoe.
110 lb. Broken Pekoe.

and can be supplied in shooks delivered at the Colombo Railway Station at R1·30 each (without nails.)
or made up (with nails) at R1·40 each.
A chest requires about 70 to 80 wire nails (1 lb.=about 380 nails.)
" 6 lb. tea lead.
" 3 oz. solder.
not quite ½ lb. hoop iron.
about 70 rose nails for fastening do. (1 lb.=about 560 nails.)

Now, provided the *hal* wood tea chest turns out to be good and serviceable,—and we can affirm that it *looks* the right thing, while the Company's Manager says the chests made of *hal* are good and compare most favourably with Indian tea boxes, of which a large number has passed through his hands,—we have here a box of superior capacity at a lower price than those previously quoted (made up with nails R1·40 each) and constructed on such scientific principles as to size that ten such boxes make up exactly the measurement ton of 50 cubic feet by which freight on tea is charged. If, in addition, the Company could manage so that each box should weigh exactly the same, so as so save the injurious necessity of bulking in the London Customs, they would deserve to be regarded as special benefactors to the tea interest of Ceylon. Perfectly seasoned wood, if not exposed to wet, ought not to alter appreciably in weight, and the weight of nails, tea lead, solder and hoop iron should be uniform. We surely are within hailing distance of the time when the quantity of tea of each kind in boxes can be so entirely relied upon, even by men so accustomed to the shady side of human nature as customs officers, that there may be no occasion to open boxes before sales, except for the purpose of taking samples.

If tea planters are grateful for having the above information placed prominently before them, the best way in which they can make a return is by supplying us, for the benefit of those interested in the new industry, with information as to the kinds of forest trees, in the lowcountry and at high elevations, which have hitherto been found best suited for the boxes, the prevalence of such timbers, and the comparative cost at which they can be felled, sawn, seasoned, and worked up on estates. It is of much importance that the use of tea driers will save the necessity of converting some of the best timber on estates into charcoal, because such timber can now be utilized for tea boxes or other purposes With railway extension, indeed, it is possible that coke may be found a cheaper and better fuel for the tea driers than firewood, the smoke from which might be objectionable. As the supply of really good timber in the hill forests of Ceylon is, after all, very scanty, information regarding the best trees to grow at various elevations will be valuable. We do not forget the lists of low and high elevation trees issued by the late Dr. Thwaites, but they were prepared without any reference to the question now being discussed. We fear the *lunumedilla* is specially a lowcountry plant, but probably trials will show that this and other suitable plants have a pretty extensive range as regards altitude.

Our present enquiries were started by the receipt of a letter from Mr. J. S. Gamble, whom we had the pleasure of meeting in British Sikhim in 1876, and who is now at the head of the Madras Government Forest Department To the Indian and botanical names furnished by Mr. Gamble, Mr. W. Ferguson has, at our request, added notes indicating whether the trees are indigenous to or to be found in Ceylon. Here are the letter and the notes :—

Madras, 3rd April 1883.

SIR,—At p. 720 of your March No. o the *Tropical Agriculturist* you take me to task for not giving the scientific names of the trees which I enumerated by their vernacular ones, as producing woods fit for tea boxes. So I send you the list with the native names perfectly corrected as to spelling. The misprints were chiefly made by the *Indian Forester*, I see. For 'Chota Kagpur' please read "Chota Nagpur.'—Yours, J. S. GAMBLE.

Indian Names.		Botanical Names.
Toon	1.	Cedrela Toona, microcarpa or glabra (*a*)
Lampatia	2.	Duabanga sonneratioides (*b*)
Semul	3.	Bombax malabaricum (*c*)
Gognidhup	4.	Canarium bengalense (*d*)
Kadam	5.	Anthocaphalus Cadamba (*e*)
Mandania	6.	Acrocarpus fraxinifolias (*f*)
Mainakat	7.	Tetrameles nudiflora (*g*)
Udal	8.	Stereulia villosa (bad) (*h*)
Kabashi	9.	Acer Campbellii or lævigatum (*i*)
Mahua	10.	Engelhardtia spicata (*j*)
Gobria	11.	Echinocarpus dasycarpus (*k*)
Chilauni	12.	Nyssa sessiliflora (*l*)
Lepchaphal	13.	Machilus edulis (*m*)
Tarsing	14.	Beilschmiedia Roxburghiana (*n*)
Salai	15.	Boswellia thurifera (*o*)

Mr. W. FERGUSON'S Notes:—(*a*) Not a native of Ceylon. Introduced in Peradeniya. (*b*) Not in Ceylon, (*c*) Katu-Imbul. Red flowered silk-cotton tree. (*d*) Not in Ceylon. (*e*) Common Ceylon tree. (*f*) Not in Ceylon. Leguminoseæ. (*g*) In Ceylon hills rare. Detiscaceæ. (*h* and *j*) Not in Ceylon. (*k*) Not in Ceylon. Bhotan, Sikkim Eastern Himalaya. (*l*) Sikkim 5,000-7,000 ft. Martaban, Java. (*m*) Native of Northern India. (*n*) Also Northern India. (*o*) In northern part of Madras Presidency, and in Bengal, this and No. 4 closely allied. We have in Ceylon the Kækuna, Canarium Zeylanicum, Thwaites.

Mr. W. Ferguson adds detailed remarks as follows:—

NOTES ON MR. GAMBLE'S LIST OF TIMBER TREES FIT FOR TEA BOXES.

I have put notes opposite to Mr. Gamble's list and I shall here refer to the nos. only, as there is no use in repeating the native and botanic names:—

1.—Introduced to Ceylon and in the Peradeniya Gardens. Same family, Meliaceæ, as the Lunu-midella.

2.—Not yet in Ceylon. D. moluccana, in the Peradeniya gardens. See Morris's list. It is of the same family as the Lagerstrœmia flos-reginæ, the Murutu.

3.—The red flowered silk cotton tree. Kattu-Imbul. Wood too weak and perishable, I should think.

4.—The family that produce the aromatic gums of the Bible. We have one in Ceylon, the Kækuna. C. zeylanicum, Thwaites See No. 15 of same family. I don't think the timber of these would be good for tea boxes.

5.—Ceylon tree, large and a quick grower. I know it well, but don't know much about its timber. It is so close an ally of the Bak-mi, which injured some Ceylon Company's tea, and about which Mr. Horsfall wrote to *Observer*, that they used to be in the same genus, Rubiaceæ.

6.—Not in Ceylon. An Indian tree. Don't know much about it. A large tree.

7.—A Ceylon tree. The only one of the order DATISCEÆ. I have never seen the tree, and failed to get a specimen of it.

8.—Not in Ceylon. Several of the family in Ceylon. I do not think any of them will be good for tea boxes.

9.—None of this genus in Ceylon.

10.—Not yet in Ceylon.

11.—Not in Ceylon. Allied to the Weralus. Bhotan, Sikkim, Eastern Himalaya.

12.—Not in Ceylon. An obscure family. This tree 60 feet high: Sikhim at 5,000-7,000 feet. Martaban, Java.

13.—One of the laurels. Native of Northern India. Kudu-Dawulu, a famous timber tree on estates in Dimbula and elsewhere, a close ally, but some of them are likely to have aromatic woods. The famous *Yaverni*, Aseodaphne semicarpifolia, of the Eastern Province. A good wood. Same family, cinnamon, camphor, &c.

14.—Not in Ceylon. Northern India. Same family as No. 13.

15.—Not in Ceylon. In northern part of the Madras Presidency and Bengal. See my note on No. 4.

See No. 13, p. 53, "Tea Cultivation in S. India and Ceylon," &c., and W. F.'s "Timber Trees."

As lightness combined with just sufficient strength to carry home a load of tea safely are the desiderata for tea-box timber, it is quite possible that experi

ence may decide in favour of trees which the writer of the notes does not estimate highly. For instance, the *Bombax malabaricum*, or scarlet-flowered cotton tree. We do not know about its rapidity of growth, but such trees as this and *Erythrina indica*, and especially the common green cotton tree, could be crammed in great numbers into a limited space of ground. We do not want *valuable* timber for tea-boxes. If it is light, so much the better, provided it will season well and stand knocking about for a few months. Objectionable aroma, juices and gum, could probably be got rid of by judicious seasonings Fire heat or steam, properly applied, can effect wonderful changes in the nature of timbers.

We add some general remarks with which Mr. W. Ferguson accompanied his notes :—

Surely by this time you and the other tea planters of Ceylon, viz., Taylor, Elphinstone, Armstrong, Jones, Mackwood, Ceylon Company, Owen, and others, have found out the *cheapest* and *best* kind of boxes, native or foreign, for packing tea in, and, if made of native woods, there ought to be a list of native names—at least of those found best fitted for the work. [Details regarding the timbers used on Abbotsford will be forthcoming immediately.—ED. C. O.] I do not think there is any use in attempting to introduce and grow any foreign tree for this purpose, as I believe we have abundance of trees which will answer equally well.

Mr. Owen sent me a list of trees some time ago, and asked me to say which of them were suitable for tea boxes. I met him in the *Observer* office, and said: "Trust a great deal to your native carpenters, who know the qualities of the different native woods. Don't use those that have *milk*, *gum*, or *acrid juice*, *resin*, &c., in the wood. Don't use heavy wood, nor one that will perish very soon, and don't let the wood have any smell of any kind, if possible."

But I fear the great bugbear is the want of proper seasoning in the log and after it is sawn before it is converted into tea boxes.

There was a regular set of saw-mills at work in the forests at Awisawella some time ago, sawing timber for tea boxes and other purposes, and the gentleman in charge, whom I met at Mr. Ward's house at Hanwella some time ago, promised to send me a list of the good and bad trees. I made a selection of 113 of the best timber trees of Ceylon, when I made the notes to Mendis's list, but I shall now include all the *real trees* of Ceylon, and finish their uses, or wipe them out as utterly useless. How in the meantime can we get lists from the different tea planters named, shewing the best tea woods they have actually used ?

We cannot doubt that the information desiderated will be supplied, so that erelong we may have a reliable list of the most suitable timbers for tea-boxes and all the purposes connected with the tea industry.

Meantime we quote from Mr. Brace's list :—

ACROCARPUS FRAXINIFOLIUS: RED CEDAR.—"The timber is flesh-coloured and shrinks in seasoning; it is light and much resembles that of *cedrela toona* and has a cedrel-aceous smell; it is known to planters by the name of Shingle Tree, Pink Cedar, and Red Cedar, and is called *mullay* here in Tinnivelly, and *kilingi* by the burghers on the Neilgherries; it is of rapid growth and well worthy of cultivation by the Forest Department" (Bedd. Flor. Sylv.). I have used this timber more perhaps than any other for tea boxes and tea house furniture in general, and if it has been well seasoned it is as good a wood as could be procured for the purpose. I am not aware if this tree is found in Ceylon, but as it is readily propagated from seed I could suggest its being introduced. I cannot urge on planters, too strongly, the advisability of planting up odd corners of their grass-lands, &c. with useful timber trees, the cost of so doing is a mere trifle, and the addition made to the value of the property say in ten years' time is very great.

ALSTONIA SCHOLARIS.—"In Ceylon it is called *rookattana*, and the wood is therefore generally employed for making coffins. * * * * * This wood, which is very bitter, is white and light, and is used for making packing-cases &c." (Bedd. Flor. Sylv.).

This would probably be found an excellent wood for making boxes.

ARTOCARPUS HIRSUTUS.—"This tree yields the anjely wood so well known on the Western Coast for house building, ships, frame-works, &c. The tree attains a large size in the forests on the Western Coast, where it abounds. The fruit is the size of a large orange, and abounds in a viscid juice, which freely flows from the rind if touched; this is manufactured into birdlime" (Drury, id.). This too is as excellent wood both for making boxes, buildings and estate furniture generally, and like its congeners as ornamental as it is useful.

ARTOCARPUS INTEGRIFOLIA.—This is perhaps the best wood for box-making of any; and is easily propagated and of rapid growth.

Beddome remarks that this tree is only found in Ceylon. Probably the timber is very similar to that of the other varieties and might be used for the same purposes.

CEDRELA TOONA: WHITE CEDAR.—Called on the Neilgherries *kal kilingi*. Drury remarks, "The wood is dense, hard, red, close grained, capable of high polish, not subjected to worms, nor liable to warp, and durable." Beddome says that "it is curiously absent from Ceylon" (Flor. Sylv.). This is a splendid wood, in my opinion, and as it is readily raised from seed and of rapid growth I would strongly advise Ceylon planters to introduce it. I never use any other wood when I can procure this at a moderate rate. There is hardly a purpose to which it may not be supplied. I employ it for leaf racks, rolling tables, &c.

LITSÆA ZEYLANICA.—"This tree is most abundant on the Neilgherries at 6,000 to 7,000 feet elevation, and is found throughout our Western Ghats at elevations about 2,000 feet, and it is equally common in Ceylon where it is called *dawrel kooroondoo*" (Bedd. Flor. Sylv.). This is perhaps the best wood when well seasoned for boxes that one can meet with at the higher elevations; quite equal to the red and white cedars.

MACHILUS MACRANTHA.—"Called in Ceylon *ullalu*; the timber is often used for building purposes; it is light and even grained and would answer as a substitute for deal" Bedd. Flor. Sylv.). This is probably a first-class wood for box-making.

TECTONA GRANDIS: TEAK.—Teak is an excellent wood for boxes when it has been well reasoned, and can be procured cheap. Though heavy it can safely be sawn much thinner than other woods. I am not aware if the tree is found in Ceylon.

TERMINALIA BELLERICA.—"Found in Ceylon and there called *bulu*. It answers well for packing-cases and coffee boxes" (Bedd. Flor. Zeylan.). This would probably answer well for tea boxes also.

It would thus appear that there are trees indigenous to Southern India which would be valuable if they could be naturalized in Ceylon. The jak tree and the del (Artocarpus nobilis) are, of course, too valuable for tea chests. So we should say of teak, unless it could be obtained in abundance and sawn into very thin laminæ. If Mr. Brace is correct, the *dawul kurundu* ought to be found useful at high elevations. But the railway is a great leveller, even of altitudes, and the time is probably coming when nearly all tea estates will be supplied with tea-boxes from the "lowcountry." A correspondent of the local "Times" writes as follows :—

The owners of tea estates would do well to begin at once the growing of suitable timber trees, as it will greatly enhance the value of their properties. Even where there is a forest reserve, it is chiefly valuable for its fuel, as the *suitable* timber trees form but a very small percentage of the forest. There are numerous kinds of indigenous fast-growing timber trees that would thrive better than the Australian gums on high estates. Jack is too heavy a wood and is not of very quick growth. Teak is as heavy, but is a harder and better timber for chests, if sawn in thin pieces and exposed for a few months in a dry place or shed. It grows faster than jack after the first year. Hullimilla, Boramel, Suriyah (tulip tree) Cutta imbul, are very suitable, and are very fast growers. The tulip tree wood is little used, being scarce, as all is bought up by carriage builders. It is light, strong, pliant and suited for tea chests, being free of resin and acids, &c. On some coffee

estates, where no timber trees are grown, fuel for coolies has to be bought and carted to the estates, and doled out pound by pound. This will occur on tea properties when the reserves are exhausted or planted up, as they will be, when the old clearings look seedy. For many more reasons the early planting of timber trees is a necessity on tea estates, and they who have omitted to do so should begin at once.

Divi-Divi.—A Ceylon planter now on a visit to Southern India writes:—"I have seen several of the divi-divi trees, and they seem to thrive well and be of considerable value to the owners, besides being also themselves ornamental trees; nor from what I saw do they seem to require anything very great in the shape of soil. Have you any seed in Ceylon, as I would be glad to send you some just to try? They ought to grow well in the compounds in Colombo, unless sea air is injurious, which I am told it is not. What a tremendous change, as regards scenery, from Ceylon to the plains in the Madras Presidency, not to mention the heat!" A little of the seed will be welcome, although locally available.

The North Travancore Planting Society, is a limited Company of five years' standing on the East Annamallai Hills, once the property of the "Puniat Rajah." It is with the view and hope of securing a good return that the several shareholders (28 in number) have invested such large sums in its purchase, maintenance and progress. The cultivation at present consists chiefly of cinchona (condaminea and pubescens) and tea. The former plantation is only three to four years old, while the latter has had its virgin crop. The Company is divided into three distinct estates; viz: "Terikulam," "Miniar" and "Talliar." The "Terikulam" estates are in charge of the manager of the aforesaid Company, while "Miniar" and "Talliar" are in charge of two separate Superintendents on salaries of R200 and 300 respectively. Of these three estates "Terikulam" is famous for its growth of cinchona, and from personal experience, I find the plants wonderfully healthy. "Miniar" for its tea, deserves equal praise. An experiment of coffee growing resulted in a failure, since the first bearing or virgin crop as one may call it, was deplorable this year. "Talliar," which was opened out three long years ago, seems a perfect sinecure when compared with the rest. Nothing grows satisfactorily and there is nothing like cinchona or tea or coffee. I would strongly urge that the idea of experimenting longer at "Talliar" be abandoned and that "India-rubber" or "cocoa" culture be *at once* substituted.—*Madras Times.*

Other Bittels as Substitutes for Hops in Beer are thus noticed in an article quoted by the *South of India Observer*:—The repeated failures in the growth of hops in England have led to many discussions on the subject of a substitute for the hop bitters in the manufacture of beer. On this point the *British Medical Journal* writes:—As a matter of fact, there is no more virtue in lupulin, the bitter principle of the hop, than there is in the bitter principle of chiretta, of calumba root, or of gentian. The one is as harmless as the other and if the flavour is equally agreeable, and the brewer can produce bitter beer which is as palatable by using their bitter principles, instead of those of the hop, we can see no valid reason why he should not do so nor any reason why his doing so should be made the subject of reproach or of regret, except perhaps to the hop-grower. Whether or not bitter beer flavoured with the vegetable bitters in question be as agreeable and as acceptable to the public taste as beer flavoured with hop, is a matter on which we are unable to form an opinion; but the allegation that they are successfully so used, appears to be a presumption that they can be substituted without disadvantage. The notion which is put forward in some quarters that beer so flavoured would be "an infusion of bitters instead of good sound beer" is mere play upon words. The alcoholic properties of the beer depend, of course, upon the formentable basis employed, and the process of melting them; they have nothing whatever to do with the flavouring bitter used. The peculiar value attached to hop-bitter is mere superstition, and one which has nothing that we know of specially to recommend it.

We do not see why the more intense bitter of cinchona bark should have had no notice from the writer in the *British Medical Journal.*

Smith's Patent Fibre Machine.—While at Messrs. John Walker & Co.'s works the other day, to witness the performance of the tea-sifting machine, our attention was attracted to the first of Smith's patent machines for separating fibres from aloes, &c., which has ever reached Ceylon. Its main principles are a revolving cylinder armed with beaters, by the latter of which the substance operated on is repeatedly struck, while a jet of water is continuously flowing through the machine and washing away mucilage, &c. The machine will be shown at work in a few days. So confident is the inventor of its merits that he has applied for the prize offered by the Indian Government for a machine to deal with rhea.

Jackson's "Eureka" Tea Sifting Machine was tried the other day, at the works of Messrs. John Walker & Co. who are agents for this as for all Messrs. Jackson & Co.'s machinery. It is claimed for this machine that it is a great improvement on all previously invented and used, and we believe we only express the general opinion in saying that it did the work expected of it thoroughly well. It consists of four trays, each nine feet long, superimposed in a framework, and its action is as closely as possible an imitation of that of ordinary hand trays, drawn hither and thither by coolies, and striking against upright beams of wood at each end of the course. The material differences and improvements, however, are, the more rapid action of the machine (as impelled by steam or water power), and the fact that, instead of a shock at each end, continuous vibration is secured by means of elastic uprights made of American elm thoroughly prepared in oil. We learned that a spare set of these is supplied with each machine, The trays, although separately pierced for four sizes of tea, are in a sense continuous. A box of unassorted tea, supplied by the Ceylon Company Limited, was put in, gradually, at one end of the top tray. It was vibrated along to the other end, and all leaf not able to fall through the meshes of the top tray was ejected by the orifice (a tin spout) for No. 4. No. 3 leaf then travelled over the second lower tray and was similarly disposed of. So to the end. No. 1 as sifted was composed of broken pekoe and dust; No. 2 was pekoe; No. 3 pekoe souchong; and No. 4 congou or something equivalent. Of course the final action of the human hand, guided by the human brain, can no more be dispensed with in tea sorting than in the sorting of coffee which has passed through the holes of revolving hollow cylinders. Red leaf and stalks will have to be picked out, and if it is desired that the dust (which is really comminuted tea of the best quality) should be separated from the broken pekoe, that process will require the aid of a hand-sieve; but Mr. Dalgarno, who is going to India on Mr. Jackson's behalf (returning to India indeed, for he obtained experience as engineer of a group of estates in Darjiling), remarked, in answer to a question on this point, that he did not see, why, with machine-rolling, drying and sifting, there should be any appreciable dust. Like all machinery calculated to do good work this machine is as simple as it is ingenious, and we cannot but congratulate tea growers in Ceylon that just as they are producing leaf in quantity, and it is important that human labor should be as much as possible economized, engineering skill has come to their aid in the shape of machinery for rolling the withered leaf, drying it, and, finally, sifting it

Correspondence.

To the Editor of the "Ceylon Observer."

ARROWROOT, CASSAVA, TAPIOCA, SAGO.

Colombo, 25th March 1883.

DEAR SIR,—If your correspondent "Cassava" (see *Observer*, Feb. 24th) attempts to sell as *arrowroot* the flour of cassava yams, he will find it will be rejected here, while in England he would be liable to a fine under the Adulteration Act. Arrowroot is the produce of a tuberous plant (*Maranta arundinacea*) and not of the cassava or manioc, of which there are two varieties, the sweet and bitter (*Manihot Janipha* and *Aipi*).

The Ceylon arrowroot is prepared by villagers in the neighbourhood of Colombo from the true plant, but they often adulterate it with cassava flour. This latter is cheaper but less wholesome and palatable. In 1842 Ceylon exported 150 boxes of arrowroot, and the export had increased up to 600 boxes in 1845. But for coffee being the chief attraction then, it would have received European support and continued increasing. As to the price realized as quoted by you, on a recent shipment, it is not unsatisfactory, for if this produce is cultivated largely on suitable land that could be *ploughed*, at 3d (English) per lb. a very fair return could be got within 13 to 14 months. The first few shipments of nearly all kinds of produce from places where they are never known before to come from fetch very low prices. So that 3½d to 4½d per lb can ultimately be realized for good genuine arrowroot shipped in large quantities. Cassava flour is called "Moussache," and is when prepared in the form of irregular masses known as "tapioca" or "tapioca sago." It is exported in the latter form and name largely from the Moluccas and Straits Settlements. The preparation here is certain to pay, as the cassava plant is of easy growth, and the yield both in weight and quantity of yams has been found equal to the average in Brazil, its natural home. Your correspondent should procure "tapioca sago" in bottles from the shops and endeavour to convert his crude cassava flour into that article.—Yours very truly,

W. PROWETT FERDINANDS.

[Whilst our correspondent has no doubt cleared up some of the confusion which exists on the subject of these substances, and their true sources, we think he has himself mixed up 'tapioca sago,' which is a term new to us. We are quite aware that the original and real arrowroot is the produce of *Maranta arundinacea* Linn., and that there are now other West and East Indian arrowroots which are the produce of other species of *Maranta*, and members of the same family, viz. *Cannaceæ*; that tapioca, granulated masses of larger or smaller size, is the produce of the manihot plant, and that, by the same process as that pursued in making real arrowroot, manihot arrowroot has been made to a considerable extent in former years at the Lunatic Asylum at Borella, in Colombo, as well as tapioca resembling that sold in the shops and sent here from England; that pearl and other kinds of sago are made from the farina in the trunks of the sago palm, *Metroxylon Sagu*, which is produced in such abundance in the islands of the Eastern Archipelago; and we rather think that our correspondent has mixed up some of the kinds of sago from this tree with tapioca and has called it 'tapioca sago.' If the real arrowroot could be grown in large quantities where it would not be destroyed by rats, its great enemy here, and where it would not be stolen by men, it might pay to grow and manufacture it in Ceylon.—ED.]

112

EFFECTS OF *HEMILEIA VASTATRIX* ON COFFEE.

South Travancore, 28th March, 1883.

DEAR SIR,—Referring to "J. R. C."'s letter in the March *T. A.* I may say that appearances here go to shew that *H. V.* does affect the coffee bean, and that very curiously. I, too, have observed results very similar to those described by "J. R. C.," although I have never attributed them to the spores germinating on the berry itself; but have been more inclined to ascribe the drying up of the young berries as the result of loss of nourishment, and the presence of *H. V.* spores on the dried fruit to their having been deposited there by the wind.

In all cases I have seen the leaves on the tips of the branches first wither and fall from the effects of *H. V.*, after which the branch gradually dies back, the berries nearest the tip being those to suffer *first without exception*. In a case of a heavy crop, however, the coffee sometimes loses the whole of its leaves, and the apparent result is the yellowing, or premature ripening, of the entire crop, whilst the berries nearest the points of the branches wither and dry up.

I am also of opinion that *H. V.* exercises an influence detrimental on apparently sound and well ripened beans, or how otherwise do you account for 5·20 bushels parchment being required for clean coffee where 4·90 bushels were before sufficient? Ancient coffee and exhausted soil *may* account for it certainly; but till it is *proved* that *H. V.* does *not* affect the beans beyond those directly influenced by the leaves and branches dying, it would be well not to advance any unsupported arguments.

It would be interesting to know if the Maharajah of his own accord noticed the scab on "D.O.N."'s coffee, or if it was pointed out to him; as if H. H. noticed the thing himself the disease must have indeed been serious.—Yours truly,

D. B. C.

FIBRE FROM HIBISCUS.

Wilson's Bungalow, 29th March 1883

DEAR SIR,—I have read Mr. W. Ferguson's very interesting account of the "Kapukinissa" fibre which appeared in the *Observer* of the 22nd ultimo. In compliance with his request, I beg to send you by miscellaneous post twigs of the two varieties of this plant having flowers, leaves and fruits on them. Kindly hand them to him, and oblige, yours faithfully,

HENRY E. DAMBAWINNE.

P. S.—I also send a specimen of "Gallehe" which is used by the people of this district in the manufacture of mats.—H. E. D.

[Your correspondent Mr. H. E. Dambawinne from Wilson's Bungalow says that he sends twigs of the two varieties of plants having flowers and fruits on them, and he adds that he sends also specimens of galehe (gal-æhæ) which is used by the people of this district in the manufacture of mats. Both the specimens of hibiscus were so miserably crushed and so badly put up that they are all but useless for identification. One of them is no doubt of the Abelmoschus section of hibiscus, but the other is of another section judging by the mutilated specimen sent. The gal æhæ consists of the stems of a sedge without roots or flowers, and but for the fact that I know the mat plant of this name I could not otherwise recognize it. It agrees for the plant which Dr. Thwaites has given as the *Cyperus corymbosus*, Rottbl., but is likely the *Cyperus tegetum*, of which large quantities of mats are made and transported from China to America. The gal æhæ is cultivated by the mat makers of the Kalutara district.—Here is a hint to all persons sending botanical specimens by post in Ceylon.

A parcel of these under four ounces and marked by Miscellaneous Post will come for 6 cents, and under 8 ounces for 12 cents. Collect specimens with leaves, flowers, and fruits on, if possible. Lay a bit of any kind of paper on a table, lay out your specimens on this as flat as you can, and do not put one over the other; lay another bit of paper above the plants, and any number of layers if you are going to send several kinds and a large packet. Then begin at one end of your mass and roll it up in a line with the stems of the specimens, and if the roll is too long double it, or keep your specimens short enough to make a handy roll to come by post. The separation of the specimens by the paper will enable them to come all right for botanical purposes.—W. F.]

NEYANDA FIBRE (*SANSEVIERA ZEYLANICA*).

Royal Botanical Garden, Peradeniya, 9th April 1883.

Sir,—The following valuation of the fibre from the Neyanda plant—*Sanseviera zeylanica*—is taken from a report obtained from London, by Messrs. Arbuthnot & Co., Madras, upon a sample from Vizagapatam, forwarded to them by the Board of Revenue of the Presidency. As so much interest is being taken in fibre-yielding plants, it may be worth giving this further publicity:—

Letter from Messrs. Arbuthnot & Co., Madras, to the Secretary to the Board of Revenue, dated Madras 29th August 1882:—

With reference to the Board's proceedings, No. 4,730 of the 23rd June, and our reply of the 30th, we have the honour to subjoin copy of a report received by us from our correspondents on the sample of fibre *Sanseviera Zeylanica* forwarded to them. If the sample fairly represents the average quality of fibre which could be obtained, it would appear to be encouraging. In continuation of our letter of the 30th June referred to above we would suggest that the Collector of Vizagapatam should place himself in communication with our agent at Bimlipatam forwarding him enough of the fibre to be pressed into a bale at our Jute Factory. From it we could calculate the cost of baling, shipping, &c., &c., and form an estimate of the cost of freight.

Copy.

London, 29th July 1882.—*Report:*—Good fibre, well cleaned, good color, but rather short. There is a little roughness, but is mostly soft and would be a very useful fibre if a steady supply could be depended on. Value per ton about £20. Discount 2½ per cent.

The "Neyanda" is a very common small aloe-like plant with mottled leaves found in most of the lower parts of Ceylon, especially in dry, stony, or sandy districts, near the sea, usually under bushes. In old botanical books it is called *Aloe hyacinthoides* and *Aloe zeylanica*. The Tamil name is "Marool" and the Telugu "Chaga" or "Saga." The fibre is commonly used here for making ropes and whips, &c., but especially for sleeping mats. Of the latter, those made in Dumbara by the low-caste people, and dyed yellow, red, and black with native quickly-fading dyes are well known sofa-ornaments.

Good accounts of the uses of the plant in India are to be read in Roxburgh's "Flora Indica" (II. pp. 161-164) and Royle's "Fibrous Plants of India" (pp. 51-56). The former states that in cultivation the leaves reach three or four feet, and I have seen wild Ceylon specimens as long. The above price is scarcely such as to attract the planters' favourable attention, but native cultivators might make it answer well. It is probable that the fine soft fibre would give an excellent pulp for paper-making.—I am, sir, yours faithfully,

HENRY TRIMEN.

Divi Divi ought to flourish specially in those arid regions of the north and east of Ceylon, where the scrub is composed of mimosa or acacia plants. The pods are of considerable economic value, as is made evident by information we find in a paper received from the Madras Government. We quote as follows:—"The board having learned that Mr. Cardozo had a small Divi-Divi plantation that was turning out very well, Messrs. Whiteside and Wilson visited and inspected it on the 9th November 1882. Mr. Cardozo has about seven acres planted with Divi-Divi, all produced from seed from two parent trees, which are about 25 years old. These two trees produced last year 560 lb. of pods, which when sold realised R18-10-0 (nett). Mr. Cardozo stated that the price in the London market varied from £13 to £19 a ton. During the three hottest months of the year, the trees are occasionally irrigated, but they are extremely hardy and thrive best on the soil that suits the Babul (*Acacia Arabica*). The trees are planted in rows, 22 feet apart.* Mr. Cardozo has had offers for the seed at the rate of R12 an ounce, and for seedlings natives are now offering him R6 a hundred. So far as information is available at present, the Divi-Divi is of great value in tanning, dyeing and making ink; for each of these purposes a different part of the pod is used. Mr. Cardozo showed the ink made from Divi-Divi. It is extremely black, does not clog or corrode the pen and does not fade. The board are decidedly of opinion, in view of the success that is attending Mr. Cardozo's experiment, that it is very advisable to encourage the cultivation of Divi-Divi as widely as possible. There are immense tracts of land throughout the Presidency on which the tree would grow well. It requires very little attention, and the price that the pods and seed command in the market, even now when the great value of the product is not sufficiently known, is very remunerative. The board recommend that Collectors be instructed to endeavour to stimulate the cultivation of Divi-Divi. The demand for it in the London market would increase, no doubt, with the supply."

Tea Sowing and Manufacture in Japan.—Mr. Robertson, of the British Consular Service in Japan, has recently translated a native work descriptive of the growth and manufacture of tea in that country. It appears that the preparation of the ground for the reception of the seed is as follows:—

"A hole about two feet in diameter is dug and well manured, earth sprinkled over this, and the seed can then be sown, the best kind of earth for this purpose is good black soil or what is known as hill soil, it should not be clayey, but friable. The ground should have a south easterly direction, and localities should be chosen with a due regard to a warm temperature, the great object is to guard against northerly and westerly winds. The land should be laid out in the same way as for vegetables that is in ridges and well manured.

The time for sowing is just about the break-up of winter and commencement of spring, when the snow is disappearing from off the ground.

The lid of a tub, about eight or nine inches in diameter, is taken (or what will do as well, the straw top of a rice basket) and in this is mixed as a small quantity of tea seed and guano—the guano is used to keep off the moles—the seed is then sown over the plantation, and the sowings covered with a little earth.

The ground is prepared in the winter in the manner as above described, and when sowing, it is as well to cover the seed with a little rice bran.

The plant shows up well in about fifty days.

The first year the plant attains to about two inches, grows to nine or ten inches in the second year, throwing out a couple of branches, and in the third year grows to about a foot and a half with five branches. It is only in the fourth year that the first year's leaves are picked."

The treatment of Japan leaf after picking seems to differ more from the Indian method of curing than any other process in the two systems of tea culture:

"The process of steaming the tea is as follows;—As soon as picked it is at once steamed, all damp or wet leaves being thrown on one side, excepting those that may be a little wet with dew. In order to obtain the proper application of heat, a few leaves are put into a shallow basket, spread out evenly, and the lid put on, the basket is then placed over a charcoal fire box or stove, a perfume is at once perceived. When the greeny smell has subsided, the leaves are removed, spread on a a piece of new matting, and fanned briskly so as to draw out the heat. After the lapse of some little time the tea is placed in a tray, and then undergoes a firing process, the length of which is regulated either by the minute hand of a watch or the beats of a pulse, and depends a good deal on the manipulator's own ideas."—*Indian Tea Gazette.*

* Too wide apart by one-half, we should think.—Ed.

NEW REMEDIES.*

BY WILLIAM ELBORNE.

Abrusprecatorius. Nat. Ord., Leguminosæ.—This plant, (bearing the well-known red seeds common in Ceylon.—ED.) was originally a native of India, but is now found in the West Indies, the Mauritius, and most tropical regions. It is remarkable for its small nearly globose seeds, which are of a brilliant scarlet colour, with a black scar indicating the hilum or place of attachment to the pods. These seeds are much used in I ndia in the arts, for necklaces and other ornamental purposes, and are employed as a standard of weight underthe name ofRati. The weight of the famous Koh-i-noor diamond was ascertained in this way. From a medicinal point of view the roots are made use of in the same manner as the roots of the liquorice plant (Indian Pharm.) An infusion of the curious scarlet seeds has long been used in the interior of Brazil as a popular remedy in the treatment of ophthalmic disorders. In some experiments made by Dr. de Wecker to test the action of this remedy, he found that a weak cold infusion made from the powdered seeds, when applied as a lotion, rapidly produced a purulent ophthalmia, of intensity corresponding to the number of applications made. The factitious ophthalmia thus produced disppeared in the course of ten days or a fortnight without any therapeutic intervention or danger to the cornea, and Dr. de Wecker is of opinion that this property possessed by the seeds, of provoking a very intense ophthalmia of short duration, could be utilized in ocular therapeutics in the treatment of granulations and conjunctival diphtheria. M. Silva Araujo having recently submitted to microscopical examination the infusion and maceration of the seed, together with the exudation produced by their use, attributes the cause of the inflammation and the purulent condition which follows the use of the drug, to the great number of gonidia contained in both preparations of the seed developing abundantly on the conjunctiva.—*Pharmaceutical Journal.*

LIME JUICE.

BY MICHAEL CONROY, F.C.S.

Lime juce is the expressed juice of the fruit of *Citrus limetta*, a member of the orange tribe (Aurantiaceæ). The tree is a thorny bushy evergreen, with handsome dark foliage of exquisite fragrance. The flowers are white, resembling orange blossoms, and their perfume is equally delicious. The tree flourishes best in a light sandy soil near the sea, and comes into full bearing in about seven years after the seed is set. It grows wild in nearly all tropical countries, but is now largely cultivated in the island of Montserrat. The fruit is about one-half the size of the lemon, with a smoother and thinner rind, oval, rounded at the extremities, and of a pale yellow or greenish-yellow colour. The exterior of the rind possesses a fragrant odour, and a warm aromatic, slightly bitter taste, somewhat similar to that of lemon. The juice, when fresh and sound, is sharply acid, with a peculiar refreshing and grateful flavour. In Montserrat the lime fruit harvest is heaviest from September to January, but a good supply of fruit is yielded throughout the whole year. Here, where the lime tree is specially cultivated for the sake of the juice, the work is done in a systematic manner with suitable machinery. The fruit, after collection, is taken to two central factories, where it is sliced by water power, and then squeezed in huge wooden presses, the juice being run into puncheons and quickly bunged up. This is a most important point in preparing the juice in a tropical climate, for if left exposed it would rapidly decompose. I am also informed that the choice fruit is alone used, and that only about two-thirds of the juice is pressed out, thus ensuring greater freedom from mucilaginous and pulpy matter. The further pressings, together with the juice of the unsound fruit, is evaporated to the consistence of treacle, and sent over to this country for the manufacture of citric acid. It is chiefly owing to these precautions that Montserrat lime juice is so much superior to that produced in Jamaica and elsewhere, where no care or supervision is exercised in its preparation.—*Pharmaceutical Journal.*

* The subject of a Report on Materia Medica read before the School of Pharmacy Students' Association. Jan. 18, 1883.

COW TREE.

The Palo de Vaca, or Cow tree of South America (Brosimum Galactodendron), grows in large forests in the mountains near Cumana, and in other parts of the seacoast of Venezuela. It forms a tree frequently over 100 feet high, and often running to a height of 60 or 70 feet before branching. The milk, which is obtained by making incisions in the trunk, is said to have an agreeable taste like that of sweet cream, with a slightly balsamic odour; it is somewhat glutinous, but said to be nourishing and perfectly wholesome. According to Boussingault the constitution of the "milk" of the Cow tree approaches very closely that of the genuine milk of the cow. At the request of the India Office we obtained from Venezuela a supply of the seeds, through the kind assistance of Dr. Ernst, Professor of Natural History in the University of Caraccas. A case of germinating seeds was duly despatched in October, 1880, to the superintendent of the Victoria Gardens, Bombay. No information of any kind has since reached Kew officially as to the result of the experiment. I extract, however, the following account from Mr. Stormont's report on the Khandesh Government Farm for 1881:—"Six small healthy-looking plants of the Cow tree (Brosimum Galactodendron) were received from the superintendent of the Victoria Gardens, Bombay, in July. Of these two were sent for trial in Dhulia, three others planted out in ordinary garden soil, and one merely shifted into a larger pot. The latter is doing well; but those planted out have made no progress—have even lost most of the leaves they had. What they may do in the hot weather remains to be seen." The home of the Cow tree in Venezuela is in 10° N. lat, and in a doubtless very damp climate. How it will fare 11° further north, with a rainfall of under 40 inches, is a not perhaps very hopeful prospect. A portion of the seeds retained at Kew germinated, and plants were sent during the past year to the botanic gardens of the following places:—Adelaide, Brisbane, Calcutta, Ceylon, Fiji, Java, and Singapore. In Ceylon the plants are reported as doing well, though slow in their growth.—*Kew Report for 1881.*

STORING IMPORTED VEGETABLE AND FLOWER SEEDS.

The following remarks are made with a view of drawing forth an expression of opinion from those who have had experience in keeping imported cold season vegetable and flower seeds in a germinative condition throughout the rainy season. Complaints are frequently made that certain seeds have not germinated, and for that reason have been classed as bad. There are many ways by which seeds may be brought to this condition, and I believe a bad method of packing and storing to be one of the most common. Seeds of vegetables and flowers, raised in this country, do not require much care in storing. If kept in a dry room and looked over occasionally, such appliances as hermetically sealed boxes, bottles, &c., are entirely unnecessary. It is very different however with imported seeds. A few days' exposure to the damp atmosphere of our rainy season is very fatal to their vitality. European seedsmen usually send out their seeds to this country in hermetically sealed tin boxes. When sent by a repectable firm, so as to arrive just when required for sowing, they will, as a rule, germinate freely. When failure occurs under these circumstances, the gardener who had charge of their management must be at fault. On the other hand, if, as is often the case, they arrive a month or two before the season for sowing, and have been kept in the sealed tin boxes until that time arrives, no one should blame the gardener, or feel surprised if they do not all come up. Packing seeds in hermetically sealed tin boxes, is, without doubt, one of the best methods for this country; for I believe their vitality is greatly injured if they remain in the boxes for a month or two after arrival. All good seeds contain a certain percentage of moisture, and the natural heat of our climate causes this moisture to be continually given off, and when confined within a sealed tin box it must condense and thereby injure the seeds. I strongly advise opening hermetically sealed boxes of seeds immediately on arrival, and transferring the contents to a well made wooden box.

Any rough box will do, provided it has a close fitting lid. The bottom of the box should be covered with a layer of charcoal dust. It is also a good plan to fill a few small bags with the same material, and place them amongst the seed packets. Charcoal is a capital substance for inhaling any moisture given off by the seeds, or any that may find its way within from the atmosphere. Bottles with glass stoppers, when used for keeping seeds, have the same injurious effects upon their vitality as hermetically sealed boxes. I have noticed that seeds, to all appearance quite dry, when placed in a glass stoppered bottle give off, within ten or twelve days, sufficient moisture to cover the inner surface of the vacant glass, with a heavy coating of dew. This is not so soon generated if common corks are used instead of glass stoppers; I suppose the cork inhales the moisture given off. When bottles are used for keeping any rare kind of seed, it is much the best plan therefore to use a common cork. This plan of opening hermetically sealed tin boxes immediately on arrival is much at variance with that adopted by other authorities, and as I consider the subject to be an important one, I shall be glad if any of the readers of the *Indian Forester* will record their experience.—W. G.—*Indian Forester.*

VANILLA PLANTING IN TAHITI.

The most precious crop here is the Vanilla, which is both pretty and lucrative, being worth about $4 a pound. It is a luxuriant creeper, and grows so freely that a branch broken off and falling on the ground takes root of its own accord; and it climbs all over the tall Coffee shrubs; the Palms, Avocada Pear, and Orange trees, and everything that comes in its way growing best on living wood, the tendrils thence deriving sustenance. It also flourishes best in unweeded grounds, the roots being thereby kept cool.

So the steep-wooded hillside is densely matted with this fragrant spice, which scents the whole air, indeed the atmosphere of the house is redolent of Vanilla. It is like living in a spice-box, as the pods are laid to dry in every available corner. They must be gathered unripe, and dried in a moist, warm place; sometimes they are packed under layers of quilts to prevent them from bursting, and so losing their fragrant essences.

All this sounds very pleasant, and only suggests light work, yet in truth this cultivation involves most exhausting toil. The plant is an exotic; it lives in these isles by the will of the planter, not by nature's law. In its native home, exquisite humming birds hover over its blossoms, therein darting their long bills in search of honey, and drawing them forth, clogged with the golden pollen, which they carry to the next flower, thus doing nature's work of fertilization.

Here the flowers have no such dainty wooers, and the Vanilla bears no fruit unless fertilized by human hand. So M. and Madame Valles, and their son, divide the steep hillside into three sections, and each morning they patiently and wearily toil up and down, up and down, again, and again, and again, in order to manipulate each blossom that has expanded during the night. "Faire le mange des fleurs," as Madame Valles describes her daily task, is no sinecure; it must be done during the hottest hours of the day, when any exertion is most exhausting. It needs a keen eye to detect each fresh blossom, and any neglected flower withers and drops. Each day the ripening pods must be gathered, and in dry weather the plants require frequent watering—an indescribable toil.

This morning Madame Valles let me accompany her on her morning rounds, whereby I realised that toil and hardship are to be found even in Paradise.—*A Lady's Cruise in a French Man-of-War, by Miss Gordon Cumming.*

COFFEE-PLANTING IN CEYLON IN THE EARLY DAYS.

(*By an Old Proprietor—Major-General Braybrooke.*)

As yet I understand that Guinea and Mauritius grasses are the only fodder, and cocoanut poonac the chief article of more nutritious food for cattle. As regards grasses, *with care and attention* I imagine that sufficient may be grown on most estates to supply all needs, as well as mana grass for bedding. In some localities also, paddy straw, natchinee stalks, &c., might be procurable, both of which, if cut into chaff and mixed with poonac and a *little salt*, would be capital food for cattle. I understand that even cocoanut poonac has become enormously dear. It is evidently most important for the interest of Ceylon that efforts should be made to grow other articles of food, &c., than now exists, and if the wealthy natives would set a good example to their fellow countrymen in the Maritime provinces, I have no doubt whatever that linseed, gingelly, cotton, Egyptian beans, lentils, different varieties of gram, Indian corn and other varieties of food for man and beast might be grown in abundance, also fine varieties of oranges, pineapples, &c., which would pay well. There are hundreds of thousands of acres of fine land under the mountains, which, but for the indolence and apathy of the Sinhalese might be turned to admirable use. I well recollect a splendid tract of country lying between Awisawella and Ratnapura (I commanded the outpost at Awisawella in 1814*) which, if the proprietors would but exert themselves, might be made a paradise of, and there are plenty of other districts equally good. I entreat the educated and wealthy Sinhalese landholders to exert themselves and disprove Heber's sentiment that in Ceylon "man alone is vile." I think also, with all due deference, that the Ceylon Government ought to do its part in this direction, by establishing experimental farms for agriculture and thereby stimulate the natives to similar exertions.

Every proprietor and really zealous manager of estates must surely feel the deep importance of doing everything possible to lessen the cost of manuring. I believe that they may do much in this direction by *careful* experiments, *carefully* watched and recorded. On almost every property there are materials, such as prunings, weeds, soda of patanas, scrub and any such thing, which, if burnt, would prove valuable mixed with the cattle manure, or even the ashes alone applied to the roots of the trees. The castor oil plant would grow readily and the seed might be crushed on the estate; with the oil in it, it would, I fancy, prove a valuable adjunct to cattle manure. With care and patience, I believe that composts may be made of equal efficacy to cattle manure in far less bulk, and therefore saving largely in its application. Ashes and any refuse animal remains, lime, sulphur, pulp, chemicals as indicated on works upon agriculture, should be tried, but, whatever is done, they should be carefully superintended and results recorded. The following fact shows how essential such care is. When bones were first taken to Ceylon I purchased and sent to my property a quantity with directions to remove the soil from the roots of the trees, to mix a specific quantity of bones with it and then to put the mixture carefully over the roots. I went up to the estate soon afterwards and found bones in all the drains and on further investigation ascertained, that, except to a few trees close to the bungalow, where they had been carelessly put in a hole near the stems of the trees, the bulk of the bones had been simply scattered on the surface of the ground and were, of course, speedily washed away. This actually occurred with two Europeans upon the estate!

BILL NYE'S HOUSEHOLD HINTS.

FAMILIAR RECIPES.

To remove oils, varnishes, resins, tar, oyster soup, currant jelly, and other selections from the bill of fare: Use benzine soap and chlorofrom cautiously with whitewash brush and garden hose. Then hang on the wood-pile to remove the pungent effluvia of the benzine.—To clean ceilings that have been smoked by kerosene lamps or the fragance of fried salt pork: Remove the ceiling, wash thoroughly with borax, turpentine, and rain water, then hang on the clothes-line to dry. Afterwards pulverise, and spread over the pie-plant bed for spring wear.—To remove starch and roughness from flat-irons: Hold the iron on a large grindstone for twenty moments or so, then wipe off carefully with a rag. To make this effective, the grindstone should be in motion while the iron is applied.—To soften water for household purposes:—Put an ounce of quicklime into a certain quantity of water. If it is not sufficient, use less water or more quicklime. Should the immediate lime continue to remain deliberate, lay the water down on a stone, and pound it with a base ball club.

*Threescore and five years ago!—ED.

To give relief to a burn: Apply the white of an egg. The yolk of the egg may be eaten, or placed on the shirt bosom, according to the taste of the person. If the burn should occur on a lady, she may omit the last instructions.—To wash black silk stockings: Prepare a tub of lather, composed of tepid rain-water and white soap with a little ammonia. Then stand in the tub till dinner is ready. Roll in a cloth to dry. Do not wring, but press, the water out. This will necessitate the removal of the stockings.—If your hands are badly chapped, wet them in warm water, rub them all over with Indian meal, then put on a coat of glycerine, and keep them in your pockets for ten days. If you have no pockets convenient, insert them in the pockets of a friend.—An excellent liniment for toothache or neuralgia is made of sassafras, oil of organum, and a half-ounce of tincture of capsicum, with half a pint of alcohol. Soak nine yards of red flannel in this mixture, wrap it around the head, and then inscrt the head in a haystack till death comes to your relief.—Woollen goods may be nicely washed, if you put half an ox-gall into two gallons of tepid water. It might be well to put the goods into the water also. If the mixture is not strong enough, put in another ox-gall. Should this fail to do the work, put in the entire ox, reserving the tail for soup. The ox-gall is comparatively useless for soup, and should not be preserved as an article of diet.—*Queenslander.*

POPLAR, VINE AND POTATO DISEASE.

The disease of the Lombardy poplar, (*Populus fastigiata,*) besides engaging the attention of the Norfolk Naturalists' Society, has been several times of late referred to in the *Field* and in the *Journal of Forestry*. A paper has lately been contributed to the *Forst und Jagd Zeitung* on this subject by Forstmeister Wiese, in which are quoted several extracts from a lecture by Dr. Jesseu, professor of botany. The disease has been observed in Germauy for about ten years, and they have accounts of its prevalence in North America, as also in England. Forstmeister Wiese observed it wherever he travelled in Dessau, Thuringia, and in Bavaria. It commences with a drying up of a few twigs at the top, or on the side, which gradually increases. Attempts have been made to pollard some of the trees affected; but without much success. Everywhere Lombardy poplars are dying off, and in some quarters it is no longer possible to get cuttings to form roots and foliage. The Lombardy poplar, for which he gives as its systematic designation the name *Populus dilatata*, was introduced into Germany from the north of Italy about a hundred years ago, probably by cuttings. Like other poplars it is dicœcious, having the flowers of each sex on separate trees. Only male trees were acclimatised in the northern *habitat*, and they have been propagated by cuttings ever since, without any opportunity of reproducing the species by seeding. Now these geatlemen say that when a cutting takes root, and the apparent result is a young poplar two or three years old, this small plant really remains a divided part of the tree from which it was taken. The cutting therefore continues to partake of the identity of the tree, and remains the same in sex and also in age. The apparently young cutting may therefore start its separate life with all the weakness and predisposition to disease and decay characteristic of an advanced age. Every species of tree has a limit to the period of its growth, and those species which grow rapidly are generally short-lived. It may thus happen that a poplar raised from a cutting approaches its age limit before it is apparently twenty, and it dies off as if succumbing to an exceptionally severe season. By this reasoning the Lombardy poplars in Northern Europe are many of them much older than they seem, and the only cure for this widespread disease would be a return to the natural method of raising from seed, or a fresh importation from Italy of cuttings from really young trees.

Similarly a local disease of two willows, *Salix alba* and *Salix purpurea*, is accounted for. There had been pollarded along the wayside, and lately when it was wished to start new trunks for pollarding, it was found that cuttings from these trees, usually so exuberant, refused altogether to flourish. Both trees are common in both sexes in Germany, and seed profusely. But it seems that for convenience they have always been propagated by cuttings taken from the old hollow pollards, until now nature is exhausted.

The vine (*Vitis vinifera*) is also adduced as a case in point. Its liability to the vine disease and to the ravages of the phylloxera is attributed to the excessive age of most of the roots at present bearing wine in Europe.

Although not mentioned in the article which has been briefly summarised, the potato disease will readily suggest itself as affording another instance of propagation by division, and where a periodical return to the method of raising from the natural seed is urgently demanded.

Successful experiments have been made in raising the Lombardy poplar from seed at Carlsruhe. In the cold winter of 1879-80 there stood, side by side in the nurscry, large saplings which had been raised from seed and plants of equal size which had proceeded from cuttings. The latter were all, without exception, frozen to death, while the seed-grown plants suffered no injury.—*Journal of Forestry.*

PLANT FOOD.

Reverting to the matter of Plant Food, alluded to in our last number, we now come to a very important question, viz., the quantity of nitrogenous food lost under existing circumstances by drainage. In the paper which has furnished the text for these remarks, the results of inquiries as to the amount and composition of the drainage-water are tabulated and commented on, in the first instance in the case of unmanured and uncropped land, and next on that which is variously cropped and manured. The amount of the drainage-water depends on the rainfall, on the physical character of the soil, its permeability and water-holding power, and on the amount of evaporation. This latter in its turn is determined by the temperature, the physical character of the soil, and is greatly increased when a crop is growing on its surface. The analyses of the drainage-water are consequently important, as bearing directly on the waste of available plant food.

During the ten years 1870-1880 the range in the amount of rainfall has been enormous, in other words, there have been extremes of drought and extremes of moisture—one period of twelve months had a rainfall of 22·9 inches, another of 42·7. In like manner the drainage collected from soil, uncovered with vegetation, has varied during the summer months from less than 1 inch to more than 12 inches, and during the winter months from nearly 4 inches to more than 15 inches, and the amount of drainage from nearly 5 to more than 26 inches. The causes of this extreme variation are dependent, among other matters, on the amount of evaporation from the surface, and this has been ascertained by subtracting the amount of drainage from the amount of the rainfall, the water removed by drainage being merely the excess of the rainfall ever evaporation. The drainage, measured at depths of 20, 40, and 60 inches respectively, is, on an average, high in autumn and winter, attaining its maximum in November or January, and low in summer, the minimum occurring in May. The following figures, extracted from one of the tables, will show the relative amounts of the rainfall, drainage, and evaporation for a year (average of the ten from 1871-1880). Thus, with a total annual rainfall of 31·4 inches, the amount of drainage in inches at a depth below the surface of 20 inches was 14, at 40 inches in depth 14·9; and at 60 inches 13·2.

So far we have been dealing with the gain and loss of water from uncropped soil, but the results so obtained are of course only partially available for cultural purposes. It becomes therefore necessary to consider the state of affairs under more ordinary conditions when powerful evaporation takes place, this evaporation being mainly due to the rapid transpiration of water through the leaves. This takes place in a growing plant under the influence of light, the roots also lending assistance by enabling the plant to draw water from depths of the soil too great to be distributed by ordinary capillary attraction. Deeply rooting plants are thus more effectual in drying the soil than those with shorter, less deeply penetrating roots. As the transpiration of water from a plant is determined by light, the amount transpired must obviously have some connection with the rate of assimilation and growth. From experiments recorded many years ago in the *Journal of the Royal Horticultural Society* it was concluded in the case of pot plants that from 250 to 300 lb. of water were evaporated for

each pound of dry substance added to the plant by assimilation during its growth. The amount of evaporation from a cropped soil, however, must always be very variable according to season and the nature of the crops.

With reference to the composition of the drainage-waters we have first of all an analysis of the soil through which the water percolates, and an allusion to the formation of nitrates in the soil by the agency of bacterial growths. These act as ferments, oxidise the ammonia-salts brought down by the rain, and bring about their conversion into nitric acid, the acid then unites with the bases in the soil, such as lime, forming calcium nitrate, &c. The ferment acts in all fertile soils that are sufficiently, but not too wet, and at all temperatures above freezing-point—the maximum energy being evinced at about 37° C. (98° Fahr.)

When rain-water, itself containing ammonia, falls on the soil, it dissolves some of the ingredients of the soil, which may be detected in the drainage-water, but fertile soils possess a great retentive power for phosphoric acid, ammonia, and potash, which substances therefore are found only in minute quantities in the drainage-water. The composition of the drainage-water varies very much according as the weather is dry or wet. The drainage-water from the relatively drier soil contains about fifteen parts of nitrogen per million in the form of nitrates. After heavy rainfall the quantity of drainage-water is increased, and at the same time the proportion of nitrates is increased. The average amount of nitrogen, calculated as nitrates, per acre, in the drainage-water for twelve months, according to the tables here given, amounts to 45·5 lb. from the 20-inch gauge, 36·3 lb. from the 40-inch, and 43·5 lb. from the 60-inch gauge, so that the loss of nitrogen by drainage must be considerable when the season is wet. These results, it will be remembered, are from uncropped and unmanured soils.

Where manure is applied and the soil cropped it had been previously ascertained that a large proportion of the nitrogen supplied as manure was not recovered in the crop, nor was it accumulated in the soil. The only conclusion that could be drawn, therefore, was that the nitrogen was washed out of the soil by the rain. To test this drains were laid in each of the experimental wheat plots, and a trench cut at right angles to the drains, so that the water flowing from these latter could be readily collected from each plot separately for measurement and analysis. In summer-time, when the field is covered by crop, drainage rarely takes place, but in October the flow generally begins, to reach a maximum in December and January.

The composition of the drainage-water has been ascertained by very numerous analyses made at different times by Drs. Voelcker and Frankland, and in the Rothamsted laboratory. We cannot enter into details upon these matters, but it will be readily understood how the time at which the water was collected and the nature of the manure employed affect the composition, and how great is the difference in the composition of the surface water and of that which flows from the saturated soil. Without referring to other ingredients, it may be stated that the quantity of nitric acid lost by drainage from unmanured but cropped land, is much smaller than that from uncropped land, the crop assimilating the nitrate formed. The ammonia of the ammonium salts is retained by the soil, while the sulphuric acid or chlorine pass off in the drainage water in combination with lime. The ammonia is converted into nitric acid almost by the agency of the bacterial ferment alluded to immediately after application in wet soils. There is a greater loss of nitrogen from the use of nitrate of sodium than from that of a corresponding quantity of ammonia. It is interesting also to note the confirmation given of the fact, established in other ways, of the importance of mingling with the ammonia applied in manures some mineral substances also; thus, in summer, there is little or no loss of nitrates from the drainage-water of the ammonia plots if phosphates and potash are supplied with the ammonia, but with an excess of ammonia and a deficiency of ash constituents the nitrates are imperfectly assimilated by the crop, and appear in the drainage-water. It would thus appear that, except under special circumstances, and for a particular purpose, it is not good economy to apply nitrogenous manures by themselves, admixture with other material being generally preferable.

With these general remarks, which will suffice to indicate its general tenor, we take leave of this memoir, which is assuredly one of the most important treatises on plant food which has been issued even from Rothamsted.—*Gardeners' Chronicle.*

POOR TEA.—There enters into the importations of tea to this country a large amount of adulterated, exhausted, and otherwise impoverished material. English law strictly prohibits the introduction of such tea into Great Britain, and in 1881, more than 44,000 packages, forbidden entry there, were exported, the most of them to the United States. Among these bogus teas are those that have been already steeped and used, and then worked over for a second use. This is a matter of great interest to all tea drinkers, a legion among the farmers, and they will approve the legislation proposed in Congress to exclude those abominable combinations.—*American Agriculturist.*

THE JAPAN RADISH is thus noticed in the *American Agriculturist*:—Radishes are the roots most universally eaten by the Japanese. The Japanese radish differs from the American in size, color and taste. It is usually from 1 to 1½ foot in length, and 5 or 6 inches in circumference, but in one of the southern islands it often reaches the enormous length of 5 or 6 feet and weighs several pounds; the color is generally white and the taste is watery and sweet. It requires a deep soil and rich manuring for its growth. It is mostly planted in August and harvested in December, requiring sixty days for its growth, although there are varieties which can be planted even in spring or early summer. Every household uses this root at almost every meal throughout the whole year. It is eaten either raw, boiled, or pickled, and may be considered as the great necessary auxiliary to the Japanese meal.

SELANGOR FOR PLANTING ENTERPRISE.—There are no Malay settlements or plantations on the high hills, which are covered with primeval forest; and I briefly allude to them with a hope that the information may be of use to the coffee planters of Ceylon and other countries, some of whom have already opened plantations in Selangor at an altitude of 2,500 feet, and whose experience in other climes has favoured the belief that these hills are well suited for *Coffea Arabica*, cinchona, ipecacuanha, jalap, tea, &c.; and they have hitherto been most successful on the lower lands in rearing young plants of Liberian coffee, cocoa, sago and other tropical products. The rainfall averages about 130 inches per annum, and due provision is made in the leases to prevent the wholesale felling of timber on the summits of hills, such denudation having very much affected the rainfall in India, Australia, and other countries. Planters need have no fear of droughts, as the rains are general throughout the year.—D. D. DALY *in R. Geographical Society's Proceedings, July 1882.*

THE EUROPEAN OR ENGLISH WALNUT.—The correspondent who recently asked if the walnut was cultivated in Ceylon will find information regarding the tree in the following extract from the *American Agriculturist*:—The profitable culture of the English Walnut in California appears to have excited an interest in the tree on this side of the Continent, as shown by our numerous inquiries regarding it. In Europe this is known simply as the walnut. Our early settlers prefixed the term English to many things they received by the way of the Mother Country, without reference to their origin; hence we have "English Walnut." It is also called, especially by dealers, the "Madeira Nut." The tree is as much an exotic in England and in Spain as it is with us, it being a native of Persia and other parts of Asia. This walnut (*Juglans regia*) is a relative to our black walnut and butternut, and, like them, forms a large tree; its leaves are smooth, the surface of the nut is rather smooth, and the husk falls away from it when dry. A remarkable variety originated in France several years ago, called *Juglans præparturiens*. The tree bears large numbers of nuts of good size, with a tender shell, often bearing the third year from the seed. The tree does not grow very large, and its peculiar character of precocious fruiting is perpetuated by seeds.

The Phylloxera, which was thought to have been stamped out in Victoria at so high a cost, has now broken out again.—*Planter and Farmer.* [Just what we anticipated, when the uprooting process was commenced in Geelong. It seems impossible to eradicate this insect past any more than our fungus.—Ed.]

Will the Tomato be found to protect orange trees from blight and aphis? Our experience points in that direction. Will some of our veteran orange growers give their views on this very interesting question? We observe that the finest and cleanest of our young trees are those near tomato plants. It may be merely accidental, or the strong aroma of the plant may be obnoxious to these insects.—*Planter and Farmer.*

Beer.—A "Bill for better securing the purity of Beer," which has been brought into the House of Commons, provides that every person who sells or exposes for sale, by wholesale or retail, any beer brewed from or containing any ingredients other than hops and malt from barley, shall post conspicuously in the same place a legible notice stating what other ingredients are contained in it, under a penalty of twenty pounds for a first offence. "Beer" is defined as "beer (other than black or spruce beer), ale and porter." —*Pharmaceutical Journal.*

Comparative Hardness of Woods.—Talking shellbark hickory as the highest standard and calling that 100 other woods will compare with it for hardness as follows:—Shellbark hickory, 100; pig-nut hickory, 96; white oak, 84; white ash, 77; dogwood, 75; scrub oak, 63; white hazel, 72; apple tree, 70; red oak, 69; white beech, 65; black walnut, 65; black birch, 62; yellow oak, 60; white elm, 58; hard maple, 56; red cedar, 56; wild cherry, 55; yellow pine, 54; chestnut, 52; yellow poplar, 51; butternut, 43; white birch, 43; white pine, 30.—*Journal of Forestry.*

Curious mistakes are sometimes made with regard to the names of drugs sent from foreign countries; thus safflower seed has been offered for sale as sunflower seed. Recently a fragrant commodity appeared in the market (*Gardeners' Chronicle*, Feb. 10, p. 184) under the name of safflower, which had not the least claim to the name, inasmuch as it was found to consist not of composite but of the finely broken leaves of a labiate plant, *Zataria multiflora*, a native of Persia, Beloochistan and Afghanistan. It was shipped to this country from Bombay, but with what object it is difficult to conceive. The odour of the leaves somewhat resembles that of thyme.—*Pharmaceutical Journal.*

Tomato Wine.—Express the juice from clean, ripe tomatos, and to each gallon of it (without any water) put brown sugar—4 lb. Put in the sugar immediately, or before fermentation begins; this ought to be done in making any fruit wine. Something of the character of a cheese-press, hoop, and cloth, is the best plan to squeeze out the juice of tomatos or other fruit. Let the wine stand in a keg or barrel for two or three months; then draw off into bottles, carefully avoiding the sediment. It makes a most delightful wine, having all the beauties of flavour belonging to the tomato; and, no doubt, all its medicinal properties also, either as tonic, in disease, or as a beverage for those who are in the habit of using intoxicating beverages.—*Planter and Farmer.*

The Cinnamon Tree in Queensland.—The Brisbane *Planter and Farmer*, in noticing a nursery, states:—We find several notes in our book which space will not admit of our amplifying. But we cannot overlook a tree to which we desire very particularly to call the attention of our readers. This is the cinnamon-tree, which has grown to perfection. It is a large shrub of about 10 to 12 feet in height, and as many in diameter from branch to branch. It is the cinnamon of commerce, and, according to Mr. Williams, will grow on any stony ridge where but little or no frost is felt. The bark is taken from the last growth just as the new shoots are being made, and is cut off precisely as bark is peeled for the tanner. We were told that a tree will produce about 10 lb. of bark, and as little or no cultivation is required after the earlier days of growth, the people of our coast country should at once enter into this industry to the extent of a score or two of trees at least. In this way a new and valuable industry might be established, and our exports correspondingly raised. [Our contemporary evidently thinks that the bark of commerce is taken from trees such as he describes. It is not, and from her old coppiced plantations, can Ceylon more than supply the world's wants.—Ed.]

Jarrah Wood (Eucalyptus Marginata).—Reporting on this wood the Chief Engineer at Adelaide, South Australia, says that it has been extensively used in the colony for many years for railway sleepers, piles, and other structural purposes. Many of the sleepers that have been laid in the permanent way for a period of eighteen years are quite sound at the present time, and show no symptoms of decay or destruction from the white ant. It is recommended that the timber should always be provided from the ironstone ranges, and not from the flats or swamps, as from the latter places it is spongy, and is liable to attack from insects both on land and in the sea. It is also a matter of importance that the logs should be felled when the sap is down, and properly pitched, by which means any tendency to splitting is minimised. Sound logs are readily obtainable from 20 to 40 feet in length, and from 12 to 34 inches square.—*Gardeners' Chronicle.*

The Tomato as Food.—Dr. Bennett, a professor of some celebrity, considers the tomato an invaluable article of diet, and ascribes to it various important medical properties. First—that the tomato is one of the most powerful aperients of the liver and other organs; where calomel is indicated, it is probably one of the most effective and least harmful remedial agents known to the profession. Second—that a chemical extract will be obtained from it that will supersede the use of calomel in the case of disease. Third—that he has successfully treated diarrhœa with this article alone. Fourth—that when used as an article of diet it is an almost sovereign remedy for dyspepsia and indigestion. Fifth—that it should be constantly used for daily food, either cooked or raw, or in the form of catsup; it is the most healthy article now in use. *Tomatos as Food for Cows.*—The plan is to mix a little bran with them—say, three quarts to a half-bushel of tomatos, when fed. They cause an excellent flow of rich and delicious milk.—*Planter and Farmer.*

The Olive in California.—It appears that Mr. Cooper, of San Barbara, San Diego, and other places, has demonstrated by his cultivation of the olive that the tree thrives and bears well in California, and also that it is profitable to cultivate it. The trees begin to pay at three years, and when five years old will pay all expenses of tillage and harvesting with a surplus, while the sixth year the crop will pay for the land, the trees, and the tillage for the five years previous, and, with good care, the increase is larger from year to year for a century longer. Indeed there are now alive in Asia Minor trees known to be upwards of 1,200 years old, and they are still in full bearing. In a pamphlet published by Mr. Elwood Cooper, the statement is made that some of his best trees, eight years old, produced 2,000 gallons of berries to the acre, and the European standard is eight gallons of berries for one gallon of oil, so that this gives a product of 250 gallons of oil per acre. The oil finds a ready market at 5 dols. a gallon, which gives an income of 1,250 dols., or £250 an acre for the best eight years' old trees in an exceptionally good year.—*Farmer.*

Layering.—Anyone having a garden to attend to should understand layering. It is a very simple operation, and also a very effective one, for many things that cannot be got to strike from cuttings may, by layering, be propagated with certainity. The operation, as most of our readers are aware, consists in inducing a branch to emit roots before it is separated from the parent plant. Many plants do this of their own accord wherever they come near the ground; others can only be made to do it by artificial means. As a rule, it is necessary to cut or in some way injure the branch where roots are required to make, and this may be done by twisting it, by taking a ring of bark off, or, as is more frequently the custom, by cutting a notch or tongue in it, and pegging the branch with the tongue open several inches under the surface of the soil. The thing should be done in good growing weather, and the best to select for the purpose is young wood about half matured. Almost anything can be got to grow by attending to all these matters, but if old wood is layered it will only succeed with plants that root freely; some, it will be found, will never do more than form a hard callus. Layers should not only be pegged down firmly, but also staked securely; these two operations are more than half the battle.—*Queenslander.*

Action of Lime in the Germination of Seeds.—Following up the researches of M. Bœhm, Messrs. Deherain and Breal have ascertained that the presence of lime is beneficial to germinating seeds, especially as regards the development of the root, and specially when combined with ulmic acid. It might be worth trying what effect the addition of lime-water might have on the germination of seeds.—*Gardeners' Chronicle.*

Buitenzorg Exhibition.—A horticultural and agricultural exhibition will be held at Buitenzorg, Java, in September next. In addition to tropical products, such as rice, coffee, sugar, spices, and the plants producing them, prizes are offered for roses, begonias, gloxinias, and other flowers. Buitenzorg has one of the best and loveliest botanic gardens of the world, and if some roving correspondent should happen to visit the island in September, he might do some service by sending us a report of the show. The Secretary is Dr. J. C. Van Nooten.—*Gardeners' Chronicle.*

Eucalypti in Italy.—In a recently issued report on the sanitary condition of Italy, it is stated that at the present time the country posssesses about 100,000 Eucalyptus plants, of which about 30,000 have been planted by the railway administrations and 70,000 by private individuals. After the proof given during the severe winter of 1879-80, the future of certain species of the tree is assured in the most positive manner. As to the beneficent effects to be derived from the Eucalyptus, it is considered certain that the plant is a powerful absorbent of moisture on wet lands, while its influence by means of balsamic emanations if not so positively ascertained, is still maintained by many.—*Gardeners' Chronicle.*

Coffee-Leaf Disease in Mauritius.—The report of the Botanical Garden for 1881 records the development of the leaf-fungus, Hemileia, in Mauritius. How it was introduced is not known, but its effects have been very serious. Mr. Storck's plan of utilising the vapour of carbolic acid as a cure for the disease is considered as probably of little use, in the face of the experiments of Mr. Marshall Ward, who placed a coffee plant in a Ward's case filled with the vapour of carbolic acid and allowed it to remain for twenty-four hours. In spite of this exposure the spores of the fungus germinated after twenty-four hours.—*Gardeners' Chronicle.*

The Orangery in England.—We have now a good crop of fruit on the St. Michael and Maltese Blood Oranges: and on some of the trees there is also a profusion of sweet-smelling blossoms. This I think makes the home-grown fruit so valuable. You can cut blossoms, green leaves and golden fruit from the trees at the same time; and surely no fruits at this season could have a more pleasant garniture. If the fruit is not yet ripe, a rather dry atmosphere with a temperature of 65 will answer best. The trees should be carefully watered, as too much of it causes the fruit to crack. It may be that the fruit has been gathered from some of the trees, and that another crop has set; in that case, syringe freely with water that has been standing for some time over the hot-water pipes, and keep up the temperature. But it ought not to exceed 65°. I fancy that 60° is better, as the fruit has a tendency to drop at this season, after it seems to have set. See that all the trees are cleaned from scale. If the stems and leaves can be well washed with soapy water, they may be kept clean for the season.—J. Douglas, Loxford Hall, Ilford, E.—*Gardeners' Chronicle.*

Coffea Arabica.—In the Palm-house at Kew a plant of the Arabian coffee, bearing a fair crop of fruit, is an object which to untravelled Englishmen is not without considerable interest. The leaves are a glossy dark green, and the scarlet berries are frequently accompanied by sweet-scented blossoms. A writer, in his *Impressions of the West Indies*, thus speaks:—"Much has been written, and not without justice, of the rich fragrance of an Orange grove, and at home we ofttimes hear of the sweet odours of a bean field . . . but not for a moment would I compare either with the exquisite aromatic odours from a coffee plantation in full bloom when the hill-side, covered over with regular rows of the shrubs, with their millions of jasmine-like flowers, showers down upon you as you ride up between the plants a perfume of the most delicately delicious description. 'Tis worth going to the West Indies to see the sight and inhale the perfume."—*Gardeners' Chronicle.*

Cropping Fruit Tree Borders.—The annual cropping of fruit tree borders with vegetables is a great evil, and some of the diseases of wall trees are due to this cause. Not only is the nutriment taken out of the border, but the spade drives the roots down beyond the reach of solar warmth, which is so essential to the proper ripening of the wood. Moreover, all fruit trees thrive and bear best in a firm soil (I do not mean an unworked soil), and especially is this firmness necessary for the peach and the apricot. If the whole border cannot be given up to the trees, at least five feet running alone the back should be left uncropped, and, beyond surface culture, undug.—E. H.—*Field.*

Sago Flour and Tapioca Manufacture in Borneo.—The foreign trade of the Sultan of Brunei's territories appears to consist of what is known as jungle produce, such as camphor, bird's nests, bee's-wax, gutta-percha, and sago flour. This last is manufactured in four factories—two in the city of Brunei, and two in Brunei Bay, which are all owned and carried on by Chinese from the Straits Settlements and Labuan. Since 1879 the value of the exports of sago flour from Brunei has considerably decreased, and this decrease is described as being mainly due to a drought that occurred in 1878, followed by extensive jungle fires extending over many miles of country. This drought lasted six months, and was the most severe that has been experienced in this part of Borneo for many years. These fires increased the actual amount of sago brought to market during 1879, as many of the palms that were not fully grown, but had been severely scorched or killed by the fires were cut down, and the raw sago extracted before they began to rot. Another important export from Brunei is tapioca. Several hundred acres of it were planted by an enterprising Straits-born Chinaman in 1879 on a low hill 2 or 3 miles from the city of Brunei. The experiment has not proved a success. Much of the ground on which it was planted was so steep that the heavy rains kept contsantly washing the soil from the roots; the soil itself is not rich, and the depredations by men and wild pigs on the roots which did grow well were very considerable.—*Gardeners' Chronicle.*

Tea Plucking.—I have heard it said in more places than one, and particularly from Indian Tea Planters who have now and again visited this district, that in Ceylon we over-pluck, this, too, not so much from the older trees but from the younger ones particularly. Now as this has not come from *one* Indian tea-planter, but from nearly all, surely their views should be received with attention instead of our calmly ignoring the statement altogether. I have a friend who is in Assam, and has been there for many years, who writes me that he cannot believe that I am getting 500 lb. tea per acre off my estate, which is a young one. He tells me that he would never pluck it up to that, but be content with 200 or 300 lb., and even off full-bearing tea he would not take more than 400 or 500 lb. at the most. Now I would ask—are we all quite sure that we are on the right tack so to speak? are we doing the correct thing and that which is likely to ultimately benefit the estate owners? That good tea estates in Ceylon will bear up to 700 lb. per acre is I think beyond doubt, but I want to know whether we are right in taking that quantity? Will it not in all probability impoverish our trees in a few years? It is an undoubted fact that the soil of most of our tea gardens or estates is not so good as those of India, and that any superiority we have, is entirely due to our climate; hot, steamy and forcing as it is *all the year round*. But is it not likely that this very excellent quality will cause our trees to flush for a few years, and so exhaust themselves? We are most of us in this particular instance, following the lead of an Indian Tea Planter, who has been among us for a few years, and who evidently has had long experience of tea; but I would ask him—has he thought deeply on this subject? has he thought that, though we have an admirable tea climate, the soil is, as a rule, poor, and most likely unable, for many years, to stand the great strain on it, viz., to produce flush after flush every 8 days for ten months of the year, to say nothing of almost renewing the entire tree every now and again after an excessive pruning? To say that tea is hardy, and likes a poor soil, is to talk nonsense.—*Cor.* "Ceylon Times."

EX-CEYLON PLANTERS IN THE FAR WEST.

We are permitted to quote from the letter of a gentleman who, after learning about planting in Ceylon, returned home and is now settled in the North-west division of the Canadian Dominion. He writes to a Ceylon planter :—

Fort Macleod, N. W. Territory, Canada,

December 5th, 1882. [By mail of 15th.]

My dear ———, —A letter from this cool clime may be welcome at ————, as it is not a cool climb up to it; you may also like to know what has become of me. I came to Canada on a visit last spring, previous, as I expected, to returning to Ceylon; but while in Canada I was strongly urged to go in for cattle-raising up here, so accordingly here I am, and from reports I get from Ceylon I am well out of that unfortunate isle as a land of settlement, though "with all its faults I love it still," and shall look forward to visiting it as soon as I can. I am situated at the actual foot of the Rocky Mountains about 50 miles N. of the American boundary, on the E. side of the Rockies, a splendid climate, fine scenery, and a very agreeable life. I have applied for a lease of some 50,000 acres and have bought some stock. Our cattle run on the open prairie all the year round. It goes down to 35° below zero in the winter, but the violent winds which are almost constant in winter blow the snow off the grass. My range lies between two rivers, both of which are full of splendid fish which give good sport: there is also sport with wildfowl of various kinds deer, bears, &c., but the Indians are very destructive to game of all sorts. Last September I took a trip to Winnipeg in Manitoba, about 1,000 miles east of this: there is plenty of fine farming country all the way, but it seemed to me to be an uninteresting country to live in. The Canada Pacific Railway is being made from the Atlantic to the Pacific through Canadian soil the whole way: it is being made at 3 or 4 miles a day, and I saw ½ a mile of track laid in 35 minutes, and we returned over the rails that our train had brought at about 20 m. an hour. About 500 m. have been finished this season in about 5 months, (Ceylon may take a lesson from this country in railway making!) This country is rapidly filling up with settlers, it has only been open for settlement quite recently: till now the Indians were troublesome, now they are quiet and peaceable. All this part of the N.W. Territories adjacent to the Rockies is let on lease for grazing purposes as it is well suited to that. * * * We have to do everything here for one's-self, from building one's log cabin to cooking one's own meals and washing one's own clothes: a change after Ceylon! The new railway, which will come near us, will place us within about 14 days of Liverpool.

Another planter sends us a cutting from a Hampshire journal from which we quote as follows :—

LIFE IN THE FAR WEST.

The following letter from an old Portsmouth Grammar School boy, who went to Manitoba in September last, will help young folk bent upon adventuring in the far West to realise what to expect there :—

Brandon, Manitoba, Dec. 4th, 1882.

DEAR SIR,—I should have written to you before but I have not had much time. I am usually at work all the week, and on Sunday I write home and rest for the remainder of the day. I will begin at the beginning by telling you that I did not like the trip across the ocean at all; nor did I relish the succeeding fourteen days' railway journey at about twentyfive miles an hour. They cannot go faster because the track is laid just in the grass of the prairie. Crossing the prairie there is nothing to be seen as far as the eye can reach. It is awfully dreary. I stopped a week in Toronto and another at the end of Lake Huron at Sarnia. There I had the finest fishing I ever had in my life. The fish were 2ft long and there were as many as you liked to catch. They bite at anything. It is really wonderful. When caught they are worth nothing, because they are so plentiful.

The journey up the lakes was as miserable as the voyage across the ocean. We were out of sight of land nearly the whole time. I got off the lake steamer at Duluth. Then I took to the train again and got to Winnipeg. I stopped there a week, and then came to Brandon 133 miles west of Winnipeg. There I went land hunting, and had to sleep out on the prairie for several nights. I can tell you times were hard. We found land, and my friend took a half section. We then went out shooting. I soon gave that up, and sold my gun. There is no real sport in this country. Prairie chickens, as big as fowls, are as plentiful as stones on Southsea beach. One has to shoot at them to make them get up. Ducks and geese are in such quantities that they require to be seen to form any adequate idea of their number. In every little pond on the prairie there are two or three hundred. When you shoot at them they just rise and look at you, and pitch again. I soon got sick of them, and went out after the muskrats. I got about a dozen, and have preserved their skin. It has a very fine fur. I met a skunk. I shot him, but I could not go near him, he stank so badly. The stink of a skunk is the worst stink I ever did smell; about a thousand times worse than H. S. Never again will I shoot a skunk, except with a rifle. I shall get some sport when I go West next spring.

I stopped doing nothing for about three weeks, paying six dollars a week for board and lodging. Then I thought I had better try to earn some money. Since then I have saved 50 dollars and earned over 120 dollars. I meet plenty of English and Irish gentlemen's sons. I have seen a London city solicitor, a provincial attorney, and a Dublin doctor all shovelling dirt into the same waggon, at the tune of 10s a day. I can tell you it is a hard life. For three weeks I was herding cattle out on the prairie. I had two dollars a day and board. My lodging was a hut: my bed was potatoes. It is all very well for fellows to sit at home and talk about the beauties of a wild life in the West, but when it comes to the real thing it is a different matter altogether. I get on pretty well, but I can tell you it is not a very fine thing to go to work in the morning when the thermometer is 17 degrees below zero. You don't know what that is in England. The cold is intense. Even today at noon in the sunshine the thermometer is 13 degrees below freezing.

You would like to wear the moccassins. They are the finest things I ever put on. The snow is so dry it does not wet them. They are made of thin buckskin, and sewn with sinews, and ornamented in front. The Indians make them. Three pairs of socks and the moccassins are required to keep one warm. Brandon is built in the Grand Valley of the Assiniboine. I can't say much for the beauty of it. It is only a few tents and shanties. Wood is ten dollars per cord and coal twenty dollars per ton. I see plenty of Indians. There are lots of Sioux near us. They are not up to much. Indians often come in from the Great Saskatchewan. They are fine men, dressed in buckskin.

This is an awful country for cold. The only comfortable place is bed. That is where I am writing this. Excuse the handwriting. Shovelling dirt for a period of time takes all the symmetry out of a fellow's handwriting. I have only seen six women since I have been in Brandon. They are very scarce here. If one goes out in the street everyone is staring at her. I should think they must be very proud to be so much thought of. I guess that is the sort of thing that satisfies the vanity of the female mind. Men out here fight like brutes. If one knocks the other down, he either jumps on him or else falls on him and bites him. They are an awful whiskey drinking, tobacco chewing lot. All they think about is land and dollars. But in this place, as in every place I have been in in America, every one is a *gentleman*. Yet the Magistrate chews and smokes in the Court. The people sit with their hats on. In church, on the wall, is "Gentlemen are requested not to spit tobacco juice on the floor!" The parson reads the sermon out of a book. It is an awful place for a civilised person to come to, but at the same time it is the place to make money in. I shall save 50*l.* next summer, come home for the winter, arrange for funds for a settlement, and then go out in the spring. I shall take lessons in bricklaying. If I were only a bricklayer I could get thirty shillings a day. I must stay indoors the greater part of the winter. I have had my nose and right ear frozen hard. Icicles form on the nose directly one goes out. But cold is not the only drawback. The water is distinctly alkaline. No water not alkaline can be had in the place. This water brings on the so-called Red River fever. They tell me it is like typhoid. Both my friends have had it. I have kept clear of it. I have not had a good drink of pure water since I have been in the country. A man has now come in with both ears frozen hard. I must stop now.

THE USES OF THE MUNGOOSE.

For years the Mungoose has done good service in the West Indies in keeping down the plague of rats infesting sugar estates, and so tending to diminish the damage done by them to the cane crops. Now we hear that its aid is being sought by the New Zealand farmers in order to mitigate, if possible, the rabbit pest, which has recently assumed alarming proportions in some parts of the colony. The Government of India has been requested by the authorities of New Zealand to collect and ship a number of mungooses for acclimatisation, and we learn from Calcutta that 100 couples are being got together in the Zoological Gardens there preparatory to shipment to their new homes. Grave doubts have been expressed both as to the capacity of the mungoose to cope with the rabbit pest in certain districts where the animals have firmly established themselves, as their fecundity is well known to be something remarkable. It is also suggested that the remedy may perhaps prove even worse than the disease. The New Zealand farmers may, however, take heart of grace from the success which attended the analogous experiment

in Jamaica and Barbados. Mr. D. Morris, in his recently published pamphlet,* thus describes its results :—

"They are now firmly established in the neighbourhood of Kingston and in every parish in the island; and even in the mountains at elevations from 5,000 ft. to 6,000 ft., with a minimum temperature of 45° Fahr. they are becoming quite common. That they can swim and dive with great facility has often been noticed; and thus streams and lagoons offer no hindrance to their dispersal. After just ten year's experience with the mungoose in Jamaica, it is an interesting question both for the sugar planter and the naturalist to discuss: what are the practical results of the experiment?

"The introduction and complete naturalisation of an animal possessing such strong predatory habits, and remarkable powers of reproduction, as the mungoose, must have an important influence on all indigenous and introduced animals capable of being affected by it. As it is well known, the mungoose, although shaped like a weasel, belongs to the civet-cat family (Viverridæ); and its disposition is as sanguinary as its habits are predatory. Its natural food consists of birds, snakes, lizards, rats, mice, and last, but not least, the eggs of both birds and reptiles. In India the destruction which it often causes amongst poultry is well compensated for by the incessant war which it wages against snakes and vermin. Even the lethal cobra falls a victim to the agility of the mungoose, which, according to eastern tradition, is said to possess an antidote, by means of which it can withstand the venom of the most deadly reptile.

"I have been at some pains to learn what the general opinion in the island at the present time is with regard to the influence of the mungoose; and, at the risk of being deemed prolix, I will give a summary of the information which I have gleaned from persons representing all kinds of industries.

"In the first place, there can be no doubt that on sugar estates the mungoose has fully realized the hopes held out respecting its power as a rat-catcher; and sugar planters all over the island speak in the most unqualified terms of the good it has done in destroying the rapacious 'cane-piece rat,' and reducing the expense of rat-catching in all its phases.

"On an estate where the mungoose had only been introduced in 1878, the attorney speaks of its usefulness as follows:—'In comparing the expenditure on an estate where I lived for some years, I find the present yearly expenditure for rat-catching shews £8, as compared with £80 spent in catching and poisoning rats, and rebuilding walls pulled down to catch rats. I take this from averages for five years before the introduction of the mungoose, as compared with last year's expenditure. This amount does not include the costs, of poisons, baits and traps, which would average fully £20 a year, making £100, as compared with £8.

"In comparing the quantity of rat-eaten canes destroyed before the introduction of the mungoose, I take the number of gallons of rum-canes ground during the crop preceding the introduction of the mungoose, and compare it with the quantity ground last year. This shows 14,850 gallons rum-cane ground before 1878, to 7,425 gallons ground in 1881, which, compared at the rate of seven leads of canes to a siphon of 450 gallons, shews eleven and a half hogsheads of sugar spoilt before 1878, compared with 5¾ hogsheads spoilt in 1881—taking twenty leads of good canes to the hogshead—or a destruction of 10 per cent. as compared with 5 per cent. under existing circumstances.' Again:—'Some of the best cane lands on the estate I have just mentioned had to be thrown out of cultivation for years, owing to the impossibility of saving the canes from rats.'

"Hence, for sugar estates, the rat question appears, for the present at least, to have been fully solved. With regard to other industries, the question is not so clear, nor perhaps at first sight so satisfactory. For instance, rats, especially the black and brown species, have always caused considerable loss to coconut plantations by attacking the young nuts on the trees, and destroying them, sometimes in mere wantonness, in immense numbers. With the spread of the mungoose, I am informed that more rats than formerly have taken refuge in coconut plantations, apparently driven away from sugar estates by the mungoose, and, as the latter cannot climb, the rats are apparently quite safe. This, I fear, will always be the case, especially with the black rat, which nests in trees and is a splendid climber. It is only in the open, were cultivation is carefully kept up, and the rats have no special shelter or trees to climb, that the mungoose is a successful rat-killer. Coconut planters are now, however, protecting their trees when grown up by placing strips of tin around the stem, about six feet from the ground after effectually clearing out the rats and their nests from the trees. Bats, here called 'rat bats,' probably do quite as much harm in some districts to young coconuts as rats; and to depredations of this kind there would appear to be no remedy.

"The cultivation of cacao will, no doubt, ultimately benefit, by the introduction of the mungoose, to a considerable extent. The peasantry have hitherto suffered so severely by the depredations of rats, that this cultivation has never been taken up by them on a large scale.

"Where large areas are planted with cacao, and where the ground is kept clean and open, the mungoose must prove of great service in checking the depredations of rats and the trees being small and low, rats would be unable to make a permanent lodgment in them.

"Similarly with coffee, which has hitherto suffered most severely from their depredations. The proportion of 'rat coffee' on some estates is probably one-twentieth of the whole crop; and it would be larger still if it were all carefully gathered and cured. The actual damage done to coffee by rats has been estimated as high as £15.000 per annum, and probably this is not far beyond the mark.

"In some districts the greater yield of coffee and cacao in recent years has been attributed more to the influence of the mungoose than to the increased area under cultivation. Certainly, the large increase of our exports in cacoa during the last five years cannot be accounted for, alone, by the increase area devoted to this culture.

"Turning now to another phase of the subject, viz., the injuries said to be inflicted by the mungoose on poultry and other domestic animals, the general opinion amongst negroes and those who have not suffered severely by the depredations of rats, is of a character decidedly unfavourable to the mungoose.

"It is but natural that an ichneumon should eat eggs and destroy chickens when other supplies fail; but from my own experience (and I have some one hundred and fifty fowls running freely about the yard) I cannot recall a single instance in which eggs or chickens have been actually destroyed by the mungoose; and it is, and has been for some time, very prevalent in the neighbourhood. Many of my correspondents, however, state the fact, and on this account the negroes destroy the mungoose wherever they find it. The evil, as yet, is not of a serious character, whatever it may eventually attain, and certainly not greater in most districts than that formerly caused by rats before the mungoose became common. At present there would appear to be no diminution in the supply or increase in the price of either poultry or eggs. It is said that the mungoose will not trouble any fowl-house near which a dog is kept, and as it is a day walker, its depredations in these respects are likely to be kept within comparatively reasonable limits."

Thus far Mr. Morris, and it will be allowed that he has put the case both for and against the mungoose very fairly. This is not a matter, however, in which there is but one opinion, for a correspondent writes to one of our daily contemporaries:—"The people of Australia are about to introduces the mungoose from India, in order that the pest of rabbits may be abated. I only hope the colonists know what they are bringing upon themselves. Some times ago a mungoose came from India in a steamer. He was a lively little urchin of about the size of a pole-cat. His coat was wiry, and each hair looked like a miniature porcupine-quill. With his long snaky body, his vicious-looking claws, his sharp nose, and his villainous eye he was like murder incarnate. As he slided about on deck, casting keen glances from side to side, and undulating over chains, or ropes, or stray blocks, he looked very fell and uncanny. At night, when the dews came down, the rats would come up to sip the moisture. That was a time of rejoicing for the mungoose. His mode of working was marvellously skilful: not even the celebrated terrier which belonged

* Which appears to be an amplification of his letter to the *Field*, which will be found on pages 206-8 of Vol. II. of the *Tropical Agriculturist*.—ED.

to Mr. J. Shaw could have equalled him. He crawled sinuously up to his victim until he was within easy distance for a rush, and then struck with unerring aim, nipping the rat just at the base of the brain. The animals rarely had time to squeak, so sudden and deadly was the onslaught. In a single watch the mungoose would leave his traces from the companion to the engine-room, and sometimes the slain were found in numbers by the fore hatches. He never began to dine until his sport was over, and then he would tear and rend with extreme emphasis and enjoyment By the time the ship got home he had established such a scare that he was obliged to go down below after his game, instead of enjoying himself on the dewy deck. Wherever a rat could enter he could enter: indeed the sailors declared, and perhaps believed, that he could go through a keyhole; and in truth that strange lithe body of his wound in and out of all but impossible places. Had he been full-grown he would not have been so useful; as if was, he nearly cleared the vessel in his time. When he came to England the troubles of his owner began. The young animal developed a singular ferocity. The sight of any small living creature made him frantic, and until a proper cage of zinc was made for him he could not be kept in confinement. At the most unseasonable hours he would escape from captivity; and when he did escape he made a sensation. He seemed to pervade the house, and his mania for getting into holes was most perplexing; for instance, the leg of a pair of trousers, with their owner in them, quite came up to his standard of a negotiable hole. If the Australians intend to let the Indian beasts go loose in their country in scores of couples, as is said, there is a sad future before the Australians. It seems to us, however, that if a single mungoose can clear a ship of rats, a hundred couples turned loose in New Zealand may make it too hot for the rabbits and so prove a great blessing to the farmers, nor is this in any way affected by the fact that the mungoose is a very objectionable pet in an English household.—*Planters' Gazette.*

TEA PLUCKING.

One of the most important operations in tea culture is the plucking or picking of the young leaves or flush. The right and the wrong mode are fully described in an article which the *Indian Tea Gazette* has republished and from which we quote as follows:—Supposing a bush, four years old or older, has been *badly plucked, i.e.*, the new shoots not allowed to develop sufficiently, but *clawed off* whenever they are big enough to be caught hold of by the plucker (this method some call "clean plucking") the consequence is, that it is full of *crow's feet*, which have all to be cut out, and the bush properly ventilated *and liberally cultivated, if not manured.* It is not to be supposed that a bush can be plucked without making *crow's feet*, though not the hard, broom-like, stumpy bunches of twigs, clearly showing premature and indiscriminate *clawing* rather than plucking. At the end of the plucking season the new shoots that grew last spring should show a clean stump, four to six inches long, branching off, again and again, somewhat like straight antlers: the entire growth being a foot or eighteen inches: so that, when the pruner cuts below the lowest fork, there will be a clean, lead-pencil-like stump left, with a couple of well-developed leaves. It is from the axils of these leaves that the finest portion of next year's leaf and wood will spring. However, if the *clawing* process has been adopted, the stumps left after pruning will be wood, at least, of two years' growth. The new shoots that spring from the visible and invisible axils on these stumps, must be allowed to grow until the *second* flush makes a very decided appearance, say an expanded and the unrolled leaf. *Then* the two and a greater portion of the third leaf can be *nipped, not stripped off.* The *modus operandi* of nipping and stripping will be fully described further on. The reason of not taking off the entire lowest leaf plucked is this,—that such an act would injure the axil at its base, and thereby prevent another shoot, the next flush, developing, as it is practically impossible to remove the entire leaf without wrenching it bodily off the stock and leaving a cavity immediately below the axil, or carrying it away altogether with the leaf so taken off. The distances measuring along the stalk will decrease gradually as leaf upon leaf develops. The greater the distance between —sometimes four and five inches and even more—the leaves on a stalk, the better. On an ill-grown flush, six leaves will be found on a stalk four inches long; on a well-developed stalk the sixth leaf will not be reached till ten inches of growth have been made. The distances between the leaves, commencing from the lowest one, being three, two and-a-half, two, one and-a-half, and finally one inch. Therefore, plucking off two and-a-half inches, leaves seven and-a-half inches, which, when pruned just above the second from the bottom leaf, leaves a stump for next year a good four inches long, with two leaves and axils? The heavier the pruning, the fewer and more vigorous; the lighter the cutting, the more numerous and less vigorous will be the first flush of the following spring. The nearer a plant approaches the indigenous variety of Assam, the fewer, larger-leafed, further apart on the stalks, and golden tinted, will be the flushes. The severer the pruning with hybrid bushes at least, the greater forbearance must be exercised in plucking the first flush. Low-class China bushes seem to require heavy pruning and "clean plucking" annually. It is little use expecting a China bush to bear a long flush, and the sooner five leaves are attained, and three plucked, the better. The difference between *plucking* and *stripping* lies in the way the fingers are used. To *pluck*, the nail of the thumb must be applied to the tip or top point of the forefinger, and the stalk or leaf *cut* through. However, in practice it will be found that pluckers, if properly looked after, will *nip* the stalk or leaf between the thumb and slightly curved forefinger, and with a sharp *pinching twist* take off the leaf or stalk *clean* enough. *Stripping* consists in hooking the forefinger round the stalk, and with an upward motion *tearing* off leaves and *axils.* It will be obvious to the reader of the foregoing remarks, that, were such a vile, lazy practice allowed, the loss in the succeeding flush would simply be enormous. Stripping can easily be detected by examining the leaf baskets as they come in to be weighed at the factory. The *whole leaves* will show *stripping*; entire stalks and no loose leaves will show *bad plucking*, in so far as the lowest leaf has *not* been nipped off, leaving a third or quarter behind to protect the axil at its base; and stalks with a bud or unrolled leaf, two whole leaves attached and one three-quarter or two-third leaf loose, will show *perfect plucking.* To make coolies pluck well, is one of the planter's easiest tasks. All he has to do is to go round and *personally show each sirdar* and *each coolie how to pluck*; and if he finds his orders not carried out, to fine the *sirdar* his day's wages, and the coolie his or her wages, and any pice due them for plucking over and above the maximum number of pounds fixed for a day's work. Extra pice should never be given *till after the first flush has been plucked.*

ATMOSPHERE AND WATER.

[Mr. J. Holloway writes:—"I send you a translation of a letter appearing in *Biederman's Central Blatt*, (a book printed in Leipsic, Germany, on agriculture and chemistry) and will thank you to insert same in your paper for the information of my fellow-planters."]

(*About the evaporation of water in the different species of soil.*)

Experiments over the influence of the elements in the different soils on the evaporation of the water.

On the opinion of the farmers the field soil consists of the following chief elements:—

1. Of sand.
2. Limestone in dust form.

3. Clay.
4. Soil mixed up by manure, compounded by orgauic matters. According to this distribution for experiments have been taken.

(1.) Sand soil, containing 100 per cent sand.
(2.) Calcareous earth, containing coarse gravel 1·6 per cent
Limestone in dust form 96·0.
Clay ... ... 2·3.
3. Fuller's earth containing coarse gravel 4·0.
Clay ... ... 95·6.
4. Horse-dung.
5. Garden-soil, coutaining sand ... ... 61 per cent.
Limestone in dust form 12·6.
Clay ... ... 20·0.
Manure-earth and manure 5·3.

From each substance the same volume has been taken: 400 C.C.M. substance free of water weighed:

Sand	... 600 g.
Calcareous earth	400 g.
Clay	... 300 g.
Manure	... 140 g.
Garden-soil	... 400 g.

The experiments continued from 20th May till 20th September without any interruption. Their results are written down in this table, which is completely copied. The given numbers characterize the qualities of the soil-elements, which have influence on the evaporation of the water; they show the satiating coefficient, relative to weight and volumes; they show the different quickness of evaporation and the space of time up to the normal drying; further they prove the natural influence of the porosity of the surface, the mechanical influence of substance, and the influence of the hygroscopicity as well by the ability of retaining water as by condensing water vapour from the atmosphere; finally they state the degree of warming by the sun rays and that of cooling by nighttime. By the examinations, the following general conclusions follow for the practice:—

1.—*Cultivation of the Sandsoils.*

Sand is saturated by a proportional small quantity of water, and dries out very quick. But the little porousness of it and the considerable compactness allow to conserve a small stock of water in the lower parts of it, and being hygroscopic enough for condensing atmospheric vapour of water on its surface. However, the upper parts of the sand grows hot very much by the influence of the sun and it absorbs only a little of oxygen from the air. Consequentl the sand-soils are not much favourable for the vegetation. They can be cultivated profitably only by ample supply of manure, by what means they get able to retain rain-water in sufficient large quantities. For growing grass irrigating is necessary. It is very profitable to roll sand-soil, being always dry and warm, to raise the resistance against becoming dry.

2.—*Cultivation of the Calcareous Earth.*

Those soils, containing lime in dust form in such quantity as to make it predominant, are very scarce; here are only calcareous and marly grounds to name:—

The calcareous soils consist of coarse gravel and limestone in dust form in smaller or larger quantities. We see that this calcareous soil is able to retain more water than sand soil, becoming dry less quick, the compactuess of it being smaller, the hygroscopic qualities only a little more considerable; finally growing less hot by the sun and airing itself better. The calcareous soils ought to be cultivated like sand soils, but they will be generally more productive, making better use of the manure than sand.

The marl-soils are dense mixtures of clay and lime-stoue in dust-form; the qualities of the clay are always predominant in slur soils, they must be treated in the same manner as the clay-soils, but the limestone will improve the excessive qualities of the clay, thus contributing to the fertility of the soil. By all meaus the presence of a considerable quantity of limestone is an element of fertility for all soils, sandy as well as clayey, not only by the named reasons, but also by helping to effect the decomposition of the mauure. From that reason soils, heiug in want of limestone are supplied with limestone and clay artificially with great success.

3.—*Cultivation of Clay Soils.*

The name clay soils is given to soils, in which the special qualities of the clay are predominant. It is sufficieut for that purpose, if there are about 30 per cent of clay. Clay is able to keep large quantities of water, without beiug too wet. it becomes dry only by slow degrees. The hygroscopic qualities of it prevent very much its becoming dry and enables it to condense large quantities of water-vapour from the atmosphere. It gets hot in the sun as much as sand, accelerating by serat, the decomposition of the manure. The clay is an element absorbing very much oxygen and therefore very favourable for vegetation. But the clay has also its faults, which can be removed by good cultivatiou. The clay soils are very damp and ought to be well drained, and by deep renovated ploughing. It can receive a great deal of manure, which being able to effect a poriness favourable for penetrating of the sun-heat and circulation of the air.

4.—*Analyses of the Stable-Dung.*

(1.) Besides the manuring effect of the stable-dung, it is able to retain the largest quantity of raining-water (110 of 100 weigh; 56 for 100 of its volume.)

(2.) An account of its great porousness it acquits itself very quick of superfluity of water; three days of fine weather are sufficient, to make it loose all excessive water.

(3.) Its great hygroscopic qualities allow it to conserve for a long time as much water as sufficient for the vegetation.

(4.) To the hygroscopic qualities of the stable-dung it is owing, that it retains even in air-dry condition 40 parts of water for 100 parts of its own weight, that water remains for supplying the plants, that is to say, the soil provided sufficiently with stable-dung, contains neither too much, nor too little of the rain water.

(5.) The stable-dung, kept in the upper parts of the soil, condenses very much water-vapour from the surrounding air to end of the uight; it receives by this dew carbonic acid, ammoniac salts, nitrates and other things important for the vegetation.

(6.) Also the stable-dung mostly contributes to makiug the soil able to absorb the sun-rays which bring life into those il.

(7.) Finally, the stable-dung absorbs more thau any other soil, the oxygen of the air, which is the strongest means for decomposing manure and the best agency for almost the whole subterrauean course of life of the plants.

(8.) It is to be added, that abundant stable manure bestows upon the soil the ability to remain moist and full of poriness.

A soil deficient of stable-dung loses by drying up very

much of its volume; it forms hard clods whereby the roots of the plants become torn and the plants die. But a soil enriched by stable-dung remains always moist and flexible, and the roots can ramify themselves in it very easily. This is known very well to gardeners, they do not spare stable-dung for tender plants.

The stable-dung is certainly the most advantageous means for improving soils and the farmers will get better crops by producing as much stable-dung as possible. The artificial manures will be always very useful for manuring, but the stable-dung and horse or cattle will be the strongest base of agriculture. Finally, stable-dung has the important faculty to condense gases and vapours from the atmosphere. This condensation proceeds of course in the upper parts of the soils, on that account it is very necessary not to bury the stable-dung too deep into the soil.

INCREASE IN RAINFALL AND DECREASE IN WHEAT PRODUCTION IN ENGLAND; AND OF COFFEE CROPS IN CEYLON.

Our own experience here in Ceylon accords with that of the vast majority of meteorologists all over the world, to the effect that, whatever the aberrations of rainfall may be, a certain average is likely to be established and maintained, if the results of five years, or, at most, ten or eleven years, are analyzed. Whether the influence of sun-spot periods is admitted or denied (and we quite feel the difficulties arising from drought in one part of the earth corresponding with floods elsewhere) certain it is that dry and wet cycles are recognized by observers, and that the periods of such cycles coincide closely with a duration of eleven years. A period of thirty or more rainy years never came under our notice until we read the following letter addressed by Sir J. B. Lawes to the London *Times*:—

PROGRESSIVE INCREASE OF RAINFALL.

TO THE EDITOR OF THE TIMES.

Sir,—At Rothamsted, 30 years ago, a rain-gauge was erected in one of the fields of my farm. As our object was not only to measure the fall of rain but also to ascertain its chemical composition the gauge was made unusually large, having an area of more than 43 square feet. The following figures give the average yearly rainfall in each of the five periods of six years:—1853—1858, 25½in.; 1859—1864, 26½in.; 1865—1870, 27 1-3in.; 1871—1876, 29¾in.; 1877—1882, 33¾in.; mean, 28½in. The progressive increase in the rainfall of each period is very remarkable.

During the same 30 years wheat has been grown continuously in an adjoining field; and in the experiment to which I am about to refer the same amount of manure has been applied to the crop each year, the object being to ascertain the influence of the climate of each year under circumstances as nearly parallel as possible. Dividing the 30 years into two periods of 18 years and 12 years respectively, the average produce of the wheat during the first period of 18 years was between 36 and 37 bushels per acre; while during the last period of 12 years it amounted only to 27 bushels per acre. From 1870 up to the present time there has been only one year, 1874, in which we have had a really good crop of wheat.

Since the beginning of last October the rainfall has been far above the average, and the wheat sown in the autumn was got in under the most unfavourable conditions; at present, therefore, the prospects for this year of an abundant wheat crop are by no means favourable.

Rothamsted. J. B. LAWES.

But for the well-known character of Sir J. B. Lawes and his coadjutors for conscientious care in taking their observations, we should have deemed a continuous increase of rainfall for a period of thirty years as simply incredible. But there are the figures, giving an average of 25½ inches for the first six years, so that probably the lowest figure was down to 23 inches. In that case—the averages shewing a continuous and latterly a rapid rise—we have an increase of from 23 inches to probably 35; for 33¾ inches was the *average* of the six years 1877-1882. The increase of rainfall established in one locality in England in thirty years is therefore, 12 inches, or equal to one-third if we take the extremes, and 8¼ inches if we take the averages of six years. A reaction may be speedily anticipated, for we submit to the better knowledge of experts that a continuous increase in rainfall for a period approaching one-third of a century is outside all precedent. The result of steadily increasing rainfall in the particular locality has been a reduction in wheat produce of considerably more than one-fourth —27 bushels only per acre in the concluding 12 years against 37 in the previous period of 18. When Sir J. B. Lawes wrote, the contest of rain *versus* sun, so far from having terminated, seemed at its worst, and it would almost appear as if the stars in their courses had been commissioned to fight against the landowners and farmers of Britain. Not long ago we read a rather flatulent paper by an American writer, in which it was assumed that American farmers, who but tickled the boundless prairies of the West in order to make them laugh into fertility, were rapidly changing the conditions of Society in England, by sapping the foundations on which rested the existence of a landed aristocracy. The very year in which that paper was written, the United States had to indent on Europe for a portion of the food required by nearly a million of immigrants who had come pouring in. As a matter of fact the farmers of Britain, with all the advantages in their favour, especially of nearness to market, would have been able to compete with the corn of America, Australia, and now India, had normal conditions of season but remained to them: had the sun but shone as brightly and warmly as was his wont, and had the rain only fallen in normal moderation: in accordance with the old character of the English climate, that it "rained legs of mutton and turnips." But the results of Sir J. B. Lawes' observations only cause us to wonder that the collapse of wheat farming in Britain has been so long delayed. We can but fear that a large portion of the farmers of Britain are in as bad case as the coffee planters of Ceylon. With the farmers the owners of land, whether directly farmers or not, also suffer; and the wise men in England who have chosen this crisis for airing the theory that all burdens of taxation should be borne by the land are comparable in logic, fairness and good feeling to Mr. J. F. Dickson, Government Agent of the Central Province, who, after making the case of the planters as bad as possible by placing the coffee crop at the minimum estimate of 150,000 cwt. (evidently gloating over the fact and what it indicated), went on to propose that on the articles chiefly used by this unfortunate class should be laid the burden of additional taxation! In his dislike of the European planters this very magnanimous official took care "to remember to forget" the truth which Sir W. Gregory repeatedly stated in public, that the remote and purely native Province where Mr. Dickson had the opportunity of making for himself a name was created and for years supported by money contributed by the planting enterprize. It is quite possible that the landholders of England have failed in their duties and deserve the retribution which has come upon them; but it is surely too much that either in Britain or Ceylon the fanatical enemies of that agricultural enterprize on which even more than commerce, the well-being of a country depends, should seize the opportunity of a providential visitation to vent their petty spite. The English figures for rainfall are interesting to us in Ceylon because we have largely suffered from the same causes of excessive moisture and deficient

sun-heat. But here, as in Britain, the longest lane will have a turning: the darkest cloud will shew a silver lining, and the depressed agricultural enterprize will revive and prosper. There is the promise that to the effects of flood a limit will be placed, while summer and winter, seedtime and harvest shall not finally fail. It is true we cannot understand the meteorological aberrations from which we suffer. But we know that even these are portions of great cosmic laws, just as hurricanes and cyclones are, and that they subserve beneficent purposes on a grand scale. If, therefore, tillers of the earth will but persevere and patiently wait for results, the reward will be as certain as disappointment and trial have been.

CINCHONA CULTURE.

Prize Essay onCinchona Cultivation. Written for the Dikoya Planters' Association by Thomas North Christie. (A. M. & J. Ferguson: Colombo, 1883.)

(Communicated.)

This is a "record of practical personal experience," and gives us the results gained during nine years of cinchona planting. It will be useful as a plain and short manual, which describes the exact position attained on the cinchona question. The author is not one of those stiff-necked persons, who lay down hard and fast rules, which, because they suit them, must, they say, be universally applicable. He leaves us a choice of several methods, letting us know which one he has found most successful, but allowing a margin where each individual must use his own discretion, and be guided by the conditions of soil and climate.

Within the limits at our disposal it is impossible to go at length into all the questions raised and answered by Mr. Christie. He discusses seed, cuttings, grafting and budding—in fact all the modes of propagating the plant. He lays stress on the necessity for careful draining:—"With cinchona the chief object is to get rid of excessive moisture, while with coffee the object has been almost entirely to stop 'wash.' This difference should always be kept in view, and close, short, steep drains made the rule."

He then describes the four varieties of cinchona treated of, namely succirubra, officinalis, robusta (hybrid), and ledgeriana. He confines himself to these, as being the kinds in which the planter is at present most interested. Officinalis he considers unsuitable to our land, though he thinks that its failure has been aggravated by want of care. Ledgeriana is the most paying variety, and, as Mr. Christie says, "there are thousands of acres of patana and forest belt land, not only in Uva, but also between Nuwara Eliya and Kandy, admirably adapted for its cultivation."

When we add another quotation, it will be seen that Mr. Christie is sanguine as to the future chances of planters in Ceylon, for he ends his essay with these words:—"Those who are now only opening cinchona estates have, I think, as good a prospect before them as the earlier cultivators had. They will have the benefit of the experience of others, and any fall in the price of bark will be counterbalanced by cultivating the choicest varieties. It must also be remembered that a dozen years hence there will be very few of the cinchonas which now exist in the country alive, and that, unless fresh clearings are opened, the Ceylon production of bark, having reached the maximum, say 3 years hence, will begin to fall."

Of the different methods of harvesting bark, Mr. Christie prefers shaving, and for obvious reasons most planters will agree with him. He does not think that it should be attempted, if trees are expected to be permanent, before the end of their fourth year.

The book as a whole is worthy of recommendation. The author lapses occasionally into some rather uncouth "planterisms," but his work does not profess to be a model of style, and he will probably defend himself as being only anxious to point out the best methods of cinchona cultivation. It is a relief to turn to it from much of the unfounded assertion which has been prominent lately on the subject of coffee weeding, and leaf-disease, and it is amusing to find among the writers on practical subjects in Ceylon one who is content with a plain statement of facts as the result of his experience. Such a man is far more likely to carry conviction with him than he who, devoid of scientific education, and prone to jump at rash conclusions, gives us as incontrovertible the theories which he derives by reasoning from isolated instances.

CACAO CULTURE.

TO THE EDITOR OF THE [DEMERARA] ROYAL GAZETTE.

DEAR SIR,—I have been told by a gentleman from "Trinidad" that the Cacao tree in that Island are much damaged by the ravages of the "Macoosie" or Umbrella Ants. I had some fifteen settlements of these ants on one estate, and I took in hand to destroy them. I tried many things most of them poisonous, and some very expensive. At last I tried "Gas refuse," (Ammoniacal liquid). I simply dug a small drill all round the settlement. (One was 62 × 37 feet), I then threw buckets full of liquid on the nests and dug up them with a shovel, and the story was done.

This is cheap and safe. Let our Trinidad fellow planters try it.—Yours very truly,—T. F. MORDLE.

The Endeavour, Canal No. 1, 7th February, 1883.

EXTRAORDINARY USE OF PAPER.—Under this heading the *British and Colonial Printer and Stationer* gives an account of the Willesden Waterproof Paper Company. We quote as follows:—"The properties this paper becomes possessed of after being treated in the way we have mentioned, are very extraordinary. It becomes absolutely impervious to moisture, weather, and rot proof. The Willesden Company, who have evidently the most implicit faith in the reliability of their manufactures, have covered a large portion of their buildings with this material, as well as applying it to a number of other uses. Fancy a system exhaust pipe made of paper! The steam, puffing away merrily while we were there, and had been in the habit of so doing, as Mr. Hall proudly informs us, more than two years. They make troughs for hot water of it; drain pipes; they dug up the earth and showed us one about a foot in diameter which had been going on for three years, buried in the wet soil, and is now without deterioration. A punt made of paper was floating on the canal. After this we went upstairs, which by the way, covered with this ubiquitous material, and saw workmen cutting it into shapes, for buckets, tents, gulley ranches, houses, drinking troughs, church doors, etc., etc., etc. After having inspected all this to our mutual satisfaction, we decended and went into the yard, where our attention was distracted from some interesting point which Mr. Hall was calling our attention to, by the sight of the yard dogs' kennel, which was made of the waterproof paper; chicken coops, and rain water barrels, all of the same material. We were hauled off into houses made of paper, inspected wheelbarrows and portmanteaux made of paper, decorations, æsthetic designs, and 4-ply roofing. Their paper makes strong, serviceable, and if coated with asbestos paint, *fireproof* roofing, besides being peculiarly suitable for an infinitude of other purposes, very foreign and remote indeed from those with which paper-makers have associated their productions, but none the less tobe admired and encouraged."

Coffee Culture in Mexico.—The cultivators of coffee are threatened with still further competition. A company has been formed in Mexico for growing and exporting coffee from Colima, which a Mexican paper before us speaks of as "one of the richest coffee districts in the world." Sixteen thousand acres have been purchased near Manzanillo, on which there are already 60,000 trees in bearing and 600,000 coffee plants from one to three years old. The plants produce each two pounds annually at a low estimate. The state legislature of Colima, with a view to encouraging the industry, has passed enactments exempting from duty all machinery, implements, etc., used in the enterprize. It has, moreover, offered a large premium for the first fifteen thousand pounds of best quality of coffee raised.—*Rio News.* [Each plant 2 lb. ! They must either be planted very wide apart or lb. of cherry must be meant. The question is one of labour.—Ed.]

How to Recognise Good Wood.—Rankine says that there are certain appearances characteristic of good wood, to what class soever it belongs. In the same species of wood that specimen will in general be the strongest and most durable which has grown the slowest, as shown by the narrowness of the annular rings. The cellular tissue, as seen in the medullary rays (when visible), should be hard and compact. The vascular or fibrous tissue should adhere firmly together, and should show no wooliness at a freshly-cut surface; nor should it clog the teeth of the saw with loose fibres. If the wood is coloured, darkness of colour is in general a sign of strength and durability. The freshly-cut surface of the wood should be firm and shining, and should have somewhat of a translucent appearance. In wood of a given species the heavy specimens are in general the stronger and the more lasting. Among resinous woods those having the least resin in their pores, and among non-resinous woods those which have least sap or gum in them, are in general the strongest and most lasting. Timber should be free from such blemishes as "clefts," or cracks radiating from the centre; "cup shakes," or cracks which partially separate one layer from another; "upsets," where the fibres have been crippled by compression; "wind galls," or wounds in a layer of wood, which have been covered and concealed by the growth of the subsequent layers over them; and hollow or spongy places in the centre or elsewhere, indicating the commencement of decay.—*Lumberman's Gazette.*

Quicksands.—A correspondent writes:—"Can you or some of your scientific readers be able to enlighten me on the general characteristics of a quicksand, its natural formation, causes and general phenomena? I find, in a book I was reading, an account of one somewhere on the north coast of Yorkshire. It appears, during the time of the tide, the whole face of the quicksand sits trembling and quivering in a manner remarkable to see, and gives one the idea of hundreds of suffocating people struggling to get to the surface and sinking lower and lower in the dreadful deeps. In shore parts it goes by the name of the 'shivering sand.' Can this be true and are there really such things as quicksands in existence?" Our correspondent should consult at the nearest library, Lyell's or any other handbook of Geology, as to the causes of phenomena such as are indicated, which certainly exist and are sources of danger. We append an extract from *Knowledge* referring to a moving hill of sand:—The Reno, Nevada, *Gazette* describes a remarkable hill of moving sand in the eastern part of Churchill Country, Nevada, about sixty miles from Land Springs Station. It is about four miles long and about a mile wide. In the whole dune, which is from 100 to 400 feet in height, and contains millions of tons of sand, it is impossible to find a particle larger than a pin head. It is so fine that if an ordinary barley sack be filled and placed in a moving waggon, the jolting of the vehicle would empty the sack, and yet it has no form of the dust in it, and is as clean as any sea-beach sand. The mountain is so solid as to give it a musical sound when trod upon, and oftentimes a bird lighting on it, or a large lizard running across the bottom, will start a large quantity of the sand to sliding, which makes a noise resembling the vibration of telegraph wires with a hard wind blowing, but so much louder that it is often heard at a distance of six or seven miles, and it is deafening to a person standing within a short distance of the sliding sand. A peculiar feature of the dune is that it is not stationary, but rolls slowly eastward, the wind gathering it up on the west end, and carrying it along the ridge until it is again deposited at the eastern end. Mr. Monroe, the well-known surveyor, having heard of the rambling habits of this mammoth sand-head, quite a number of years ago, took a careful bearing of it while sectioning Government lands in that vicinity. Several years later he visited the place, and found that the dune had moved something over a mile."

Indian Coolies in Mauritius.—Some doubts prevent us being content to believe that the rose-coloured picture drawn by Mr. Trotter, the Protector of Immigrants in Mauritius, is the representation of a true state of things. The Lieutenant-Governor of that island is however satisfied; and upon these grounds. That first, the Protector writes,—we quote his report for 1881-82—"the relations existing between the Indians and their employers are most satisfactory. No single case of ill-usage came under my notice during the past year (1881), and I was surprised to find that on many estates in the island no complaint has been made against any of the servants for several months; and that on some no complaint had been preferred for 2, 3, 4, and 5 years. . . . . As a general rule the planters are kind to their labourers, and do all in their power to make them comfortable and contended:" that, secondly, there is a steady decline in the number of Indian immigrants who return home; that the numerical equalization of female to males in the colony has reached the satisfactory point in its process which had been obtained in Bombay and Calcutta; that also a decrease of written engagements, of vagraucy, of desertion, of convictions before stipendiaries, is to be noticed. All these decreases are matters for congratulation, but one or two considerations should not be lost sight of. Besides the fact of an abnormal suicide rate (42 in 1881 against 33 in 1880), it is a singular coincidence that during 1881 not one Government immigrant should have gone to Mauritius or to Jamaica, as we pointed out yesterday. As regards Mauritius, such an occurrence has been unknown for forty years past, though, it is fair to add, it has not taken place during 1882-83. Again, Mr. Trotter does not say whether any complaints have been made against the planters by their coolie labourers nor does he say whether any planters have been convicted before stipendiaries of any harshness, cruelty, or fraud. Mr. Trotter, however, does confess, and the Lieutenant-Governor agrees with him, that the entire medical system and the system of coolie-children's education demand a recast of the Labour Law of 1878. The anomaly of medically separating sugar plantations from the rest of the area in a sanitary scheme is admitted; and the Lieutenant-Governor sweepingly declares "that the whole medical system of Government is confessedly confused, expensive, and incomplete."—*Pioneer.* What we gather from the tone of Mauritius press is that the planters complain of the wages which the coolies are able to command and that Government should permit them to reside in the island without entering into labour engagements.

The Rainfall on the Serra do Mar above Sao Paulo, the district in which the Santos coffee is grown, is copious, as will be seen from the following figures :—

1873	...	131·4 inches.	1878	...	145·3 inches
1874	...	157·0 ,,	1879	...	73·3 ,,
1875	...	143·9 ,,	1880	...	160·5 ,,
1876	...	121·0 ,,	1881	...	168 9 ,,
1877	...	141·6 ,,			

It will be seen that for the five years ended 1877 the range was from 121 inches to 157, the average being about 140. In the past four years the seasons have been very irregular. Only 73 inches in 1879 must have meant drought, while the reaction to 160 and 168 led, as we know, to serious railway slips. The average for the four years is nearly 137 inches. The average for the nine years is somewhat under 139 inches: a good rainfall for coffee.

How coffee was killed out in Dominica 40 years ago is of interest to Ceylon planters, but the notice given at the time by the local *Courant* was not very full :—

The first intimation of the presence of a blight on the coffee plantations that we find in the public records of the country, is contained in a speech of the Governor of the island, Sir J. Murray Macgregor, to the legislature on March 3rd, 1836. His Excellency says that the effects of the late tempest—the hurricane of 1834—are "aggravated in many instances by the ravages of the white fly, and it is anxiously to be hoped that some plan for the adoption of the legislature may be devised with the view of assisting the sufferers and accomplishing the destruction of the insect that so mischievously infests the coffee plantations.

"The medical gentlemen of the island are about to investigate this subject, and it is impossible to doubt the disposition of your House to afford every practicable encouragement to so laudable an undertaking.'

Notwithstanding this strong recommendation, nothing seems to have been done, and the following extract from a Dominica paper of 1837 will show the extent of the calamity which overtook the island:—"It appears that the exportation of coffee for the twelve years preceding the hurricane of 1834 averaged 1,400,000 pounds, and has diminished from 2,177,558 to 396,315 pounds; add to this that the exportation of the present year is not expected to exceed 200,000 pounds! A brief account of this frightful failure of one of our staple productions cannot prove uninteresting. About the middle of 1833 it was first observed on a few properties that the leaves of the coffee trees were attacked by a very minute insect, and that in a short period of time the leaves attacked, withered and fell off—this, which was denominated the coffee blight, soon spread through the other estates, and so rapid was its progress that the crop of 1834 would have shown a very sensible diminution had not the hurricane of that year, by sweeping off the entire product of the trees, rendered any calculation of the effect of the blight impossible. Some idea may be entertained of the apprehensions of the planters on this head from the fact that many of the most respectable among them would have been reconciled to the entire loss of their crops and to the total destruction of large patches of their cultivation, had the hurricane also effected the destruction of the pest they so much dreaded. For a few months after that event there was no appearance of the blight, but no sooner had the trees recovered from the severe shock they had sustained and put forth fresh vegetation, than the formidable foe reappeared with the new leaves, and has since continued its ravages until there scarcely remains a single coffee estate in the Island on which one half of the trees are not already dead, and the remainder so enfeebled as hardly able to bring to maturity the little fruit they put forth. This insect does not confine itself to the grown-up trees, the youngest plants in the nursery are equally subject to its attack, even to the very cotyledons as they appear above the surface of the earth."

As our readers are aware, the only connection of an insect with leaf-disease is a beneficial one—an insect feeding on the fungus. We know the ravages of one insect plague, —the "bug" or scale insect; but happily we know nothing and we may be spared the knowledge of the "ravages of a white fly." It is just possible though that the white fly was a mere accompaniment of a fungoid blight.

Natal Cotton.—The following opinions of experienced persons in England on Natal-grown cotton have been obtained by the Union Steamship Company, and handed to us for publication:—No. 1 is very clean, of good colour, and of fine staple, but the staple is short and weak and rather irregular. It is not suitable for higher counts than 30s. weft. I should value it at 5¾d. today, and would give that price for it, but not more. No. 2 is worth in the market fully ¼d. per lb. less; it is of worse colour, and weaker and more irregular in staple. The above samples seem inferior in staple to those last sent.—*Natal Mercury.*

Tea.—The following account of the "powder tea" of Japan may be interesting to our readers :—"The same plant as that which yields the ordinary familiar teas of commerce produces this, only the shrubs selected are old, and must for the purpose have been subjected to a system of very copious manuring to the extent of ten applications per annum. The plucked leaves are for a few seconds exposed to a current of steam, dried by spreading out on a mat, and afterwards subjected to a similar round of manipulation as other tea, the finished product being immediately enclosed in air-tight metal jars. When required for consumption the necessary quantity for the party is withdrawn, slowly reduced to powder in a handmill, and for every individual a quarter of an ounce is removed on the tip of a feather to the cup, into which boiling water is poured. The mixture is now agitated with a wooden whisk, in the manner adopted with a cup of cocoa, until a drooping head of froth hangs over the vessel, when the fragrant nectar-like fluid is absorbed acording to the fnacy."—*Indigo Planter's Gazette.*

Insects Visiting Flowers.—The scientific writings of Darwin, Lubbock, and Hermann Müller relative to the part played by insects in their oft-recurring visits to flowers have of late years attracted much attention. The subject, in fact, has created a taste for observation, and an incentive has been given to watch the frequency of visits of various species to certain flowers and especially the insect's choice of coloured flowers. While the mere registering of visits may seem comparatively simple, the reason why insects show a preference to alight upon flowers of a certain colour, or on certain species of plants, is a much more complicated problem than at first it would appear. Two papers read at the last meeting of the Linnean Society (March 1st)—one by Mr. A. W. Bennett, "On the Constancy of Insects in their Visits to Flowers," and the other by Mr. R. M. Christy "On the Methodic Habits of Insects when visiting Flowers"—show that a strict watch and ward is being kept on the movements of the busy bee and its kindred. Mr. Bennett states that butterflies show but little constancy in their visits, citing a few instances only to the contrary; but according to him, to a certain extent, they seem to have a choice in colour. The Dipteria exhibit greater constancy, though by no means absolute. The apidæ, especially the hive-bee, manifest still greater constancy.....From these data he infers that the ratio of increase is in proportion to the part performed by the insects in their carrying pollen from flower to flower. Mr. Christy records in detail the movements of 76 insects, chiefly bees, when engaged in visiting 2,400 flowers. He tabulates the same, and concludes therefrom that insects, notably the bees, decidedly and with intent, confine their successive visits to the same species of flower.....According to him also, butterflies generally wander aimless in their flight, yet some species, including the fritillaries, are fairly methodical in habit. He believes that it is not by colour alone that insects are guided from one flower to another of the same species, and he suggests that the sense of smell may be brought into play. Bees, he avers, have but poor sight for long distances, but see well at short distances.—*Athenæum*, March 17th.

CINNAMON PRODUCTION AND SALES.

TO THE EDITOR OF THE CEYLON "EXAMINER."

DEAR SIR,—I notice a letter in the columns of the *Observer* signed "K. G." on Cinnamon Cultivation, which is evidently written by an old stager. I am at one with him in his statement that small native holdings turn out little, if any, chips. For this reason, that in such places peeling goes on almost all the year round, and no sticks are allowed to grow "coarse." It is different on a large estate. During the peeling season, the estate is gone over once, and very seldom twice. For a variety of reasons, often unexplainable, a certain proportion of sticks do not peel. They remain till the next crop, when if they are peelable they are cut and peeled, or if they have passed the peeling stage and have turned "Katta," they are ent down by the pruners, and the bark converted into chips.

In former days when cinnamon was carelessly quilled and the 4th quality cinnamon was made half the length of the other qualities, and as thick as a child's arm, the practice "K. G." refers to of getting peelers to cut coarse sticks first was no doubt very good and profitable; but in these times of severe competition, when every man strives to excel his neighbour in the fineness of his quill, and none but cinnamon of fine make is saleable, or at least saleable at a price to leave a margin of profit, however small, the cutting of coarse sticks is next to useless for quilling purposes. Often and often have I cut sticks of mediocre coarseness to have quilled for 4th quality cinnamon, and have signally failed, owing to the bark not folding in. This wasn't a drawback formerly, when it wasn't essential for the quills to be closed and the heart hid from view. Now, Sir, I am of those who think that the loss of these coarse sticks, and in fact of the coarser qualities of cinnamon and of chips, is a positive gain. Less cinnamon, but of finer quality, will be thrown into the market, and is bound to fetch higher prices, and higher prices will more than compensate for the withdrawal of coarse cinnamon and chips. I have been consistent in this belief and I have acted up to it. Unfortunately solitary efforts cannot stem the tide, and coarse cinnamon and chips are shipped in large quantities. "More cinnamon, more money," is analogous to the deep-rooted belief of the ignorant peasant, "more trees to the acre, more crop." Acting up to this belief he stocks a patch of ground with trees that will more than suffice for four times the acreage, with the result that the plants choke each other, and have an upward race for light and warmth, and bear little or no crop. This in no way shakes his belief in his system, and he exultingly speaks, not of the extent of his land, but of the number of trees it contains. So with cinnamon proprietors, men of education, they fail to see that when the demand for their produce is limited, a limited supply will help to keep up prices. Facts and figures have been placed before them in vain. It is a crying shame that when the principal growers of cinnamon are the prominent members of an Association, that Association, from want of unanimity, is powerless to effect a change for the better.—Yours truly, B.

LOSSES OF NITROGEN IN DRAINAGE WATERS.

From a letter by "Agricola" in the *Field* on this subject, we take the following extracts:—

There cannot be the slightest doubt that the heavy scourings in summer and autumn, which have proved such striking features in the last few years, are devastating in washing from the soil a great deal of soluble fertility. Even the more illiterate of farmers are well aware, from observation and experience, that such is the case; but, after all, these scourings are limited as to the actual injury they can do; while, on the other hand, wherever not absolutely excessive, the fact cannot be too strongly borne in mind that rains are calculated to be quite as beneficial, even chemically considered alone, in bringing down manure from the clouds, so that there is compensation even here.

And here comes to the very front the reflection of Mr. Jamieson, that the actual proportion of manure in soils which is actually soluble for the purposes of plant development is absolutely unknown, which naturally embodies another conclusion, that the actual proportion liable to be washed out by heavy rains cannot be estimated very definitely or concisely as yet. The bag and baggage of the agricultural army may be great or small; but the question does not bear on the bulk of the equipments, but only on the proportion liable to be lost. And herein it is to be found that the heavy *impedimenta* or stores as appearing in humus or farmyard dung, or animal manures of any kind, have ten times the chance of withstanding the remorseless scourings of the storm-cloud than the light, volatile chemical mixtures, which, however valuable as dishes ready prepared for weak, sickly plants, may easily be swept away and lost ere they can be devoured and assimilated.

If a man or animal feeds on an excess of nutriment, the portion which cannot be assimilated by the organic system passes off as waste, and thus it must always be when the soil is fed; only there is an all-wise provision in nature that the insoluble portion or the plant food, of which farmyard dung and animal manures largely consist, are stored up in the interstices until wanted; only the energy of soluble fertility which cannot be taken up with sufficient rapidity by the roots of plants, is liable to be washed out by rains, and the farmer must endeavour to guard against this evil by employing nitrate of soda and sulphate of ammonia in small doses, and always in the spring.

This article commenced with Mr. Jamieson, and it may profitably end with him, for, at the annual meeting of the Sussex Association, he remarked on the fact that many of the soils which are now washed by the rains are the richest, while the arid and sun-baked are usually characterised by a far less amount of fertility. In alluding to the beautiful climate of the south of England, and the ability of farmers to grow a large amount of catch crops than in Scotland or the north of England, Mr. Jamieson remarked: "These good points are accompanied by certain evils, for the continuous heat burnt up a quantity of the decaying vegetable or animal matter, and, in doing this, a large proportion of nitrogen was dissipated." And again he said: "They did not seem to have in the soils of Sussex more than half of the nitrogen they had the benefit of in the soils of colder climates." Here we have nitrogen losses and infertility attributed to the very opposite influence. While the rain when it raineth every day is represented at Rothamsted as a pitiless scourger of fertility and an abstractor of wealth from farmers' pockets, a Scotch chemist, coming over the Border from the carses, moors, and fells, on which the clouds continually discharge themselves by bucketfuls, thinks that the sterility of the south country bears testimony to the blessing underlying all such sousings; but, on the other hand, falls into the error of abusing the glorious sunshine, and deeming it a misfortune to be subject to nature's warming embraces. Probably in the end it will be found that nature is not so unfriendly to mankind and the arts of husbandry as our savants at present think. We are only just beginning to understand her laws and pry into her secrets. If fertility is liable to be washed out of the soil, it is brought back again in the rain and dew; and to whatever extent the sun may burn up decaying vegetable matter, it imparts new vigour to plant development, and is the life and soul of the world. Both sun and rain may do some harm in their severest visitations, but least to those who know how to trim their sails to the gale, and to be prepared for either vicissitude. [This seems to be the true philosophy.—ED.]

THE USE OF MATE TEA IN SOUTH AMERICA.

Our last number contained some curious illustrations of the effects produced by the drinking of maté in Patagones, and generally speaking it is the universal beverage throughout a large portion of the South American continent, including Paraguay, the Argentine Republic, &c. The following is an extract of what appears in our article above alluded to:—"That a people can become too temperate may be as great an anomaly as that they may be too virtuous. If Glasgow was as temperate as Carmen de Patagones, query, would they build as many steamers on the Clyde? There are no Goughs or Father Matthews needed on the banks of Rio Negro, but I note it in my tablets that where there is most industry there is most intemperance, ergo, industry breeds intemperance, and so it is in nearly all the affairs of life, the alloy is met with somewhere. Maté breeds idleness, beer industry, whisky

revolt—elect as you may. On the face of the globe there is not to be found a more temperate town than Patagones. But vegetables there are none, fish only once a week, although the river under their very nose is teeming with trout; carne, carne, carne, no potatoes, and hence no go in the people; no peas or beans, no porridge, and hence no grit in the character. The upland sloping deck of the hill on which Patagones is built is the same today as in the last century. It seems that Nature's bounty satisfies the breasts of the sons of Patagones: their bliss is small since it is only what sense alone bestows. It is essentially sensual, and when we survey the fine tall poplars that skirt the river, the rich vegetation of the river's valley, the florid beauty of the Islands above the town, the groves and fields with which Nature has decked the south side of the river, and think that in the whole town there is not to be found an onion or a potatoe, we fear we must accept the fact that man's industry is the only growth that is checked in this unsurpassed zone of mateism, yerbasim, and temperance."

We leave it to Sir Wilfrid Lawson and other advocates of teetotalism to account for this particular trait in human nature, but that the use of mate is suitable to the habits of some classes of people cannot be denied. In writing of the Paraguayans, it is stated, they are "insensible to stimulants," and mate is their general beverage—to be found ready in every domicile, and at all hours of the day, as well as of the night when desired. It is prepared in little round bowls or cups, with silver tubes to sip it through, those generally used being made from the shell of the coconut, and to refuse a bowl of maté is not considered polite. There is a certain degree of astringent about it, not always agreeable to strangers, but it is no doubt a healthy decoction. Mate was formerly the chief source of Paraguayan revenue, but the long, destructive war, seriously interfered with its growth, from the effects of which it is now slowly recovering. In Mr. Hadfield's notice of Paraguay, 1854 (page 350), occurs the following:—"There is also, however, another and not in considerable branch of revenue, viz., the monopoly enjoyed by government of the sale of maté, or Paraguay tea. It purchases this herb as prepared in the forests of the State, and when well packed and in good condition, at a given price, and disposes of it to the merchants for exportation, as well as to the consumers, at the rate of seven rials per arrobe." "The use of maté is further illustrated by Mr. Hadfield in the same volume, page 311:—"Mr. Hopkins also, I understand, contemplates improvements in the preparation of the famous Paraguay tea, maté, that will, if possible, enhance its popularity throughout South America, where there is scarcely a meal taken without it in a house with the least pretensions to respectability or refinement and elegance and adroitness in sipping it, through a tube or reed, something after the fashion adopted in the Yankee beverage, known as a sherry-cobbler, affords scarcely less opportunity at a *tertullia*, or evening party, for the display of breeding, than does the use of the fan in Spain. The taste of maté is not at all dissimilar to that of green tea, but without the acrid flavour of the Chinese infusion; and it is not improbable that Mr. Hopkins may render it a very acceptable addition to our drinks in this country; for it would, at least, from an agreeable variety to the somewhat limited round of compounds now in vogue amongst our temperance preachers and practitioners." Brazil is now a strong competitor with Paraguay in the purduction of mate, large quantities being grown in Paraguay and other parts of the interior, where the beverage is as often met with as coffee.—*South American Journal.*

SCREW-PINE; OR THATCH-TREE OF POLYNESIA.

The appearance of this tree is very remarkable. The spiral arrangement of its long, sword-like leaves, suggests the idea of an enormous screw It is known to botanists as the *Pandanus odoratissimus**: it is called by the natives *Ara*. It sometimes attains the height of forty-five feet. The male and female flowers are on different trees. The great bunches of the former—of a light-yellow colour—finely contrast with the deep-green foliage of the tree. Numerous red and yellow fruits, nearly round, and weigh ing from seven to ten pounds apiece, remind one of enormous pine-apples. Stout aerial roots, with cup-like spongioles, shoot down from the highest branches of old trees to the earth, thus supplying them with additional support and nourishment. One is amazed at the immense weight of trunk, branches, foliage, and fruit sustained by a number of prop-like roots, some five or six feet above ground. This wonder is often increased by seeing the trunk terminate above ground. The narrow leaves—sometimes seven feet in length—are armed along the edges and midrib with sharp hooks. Native lads angle for shrimps with these tiny hooks. The screw-pine grows everywhere in the Pacific, less commonly on the shores of New Guinea and the adjacent islands. Like the cocoa-nut palm, it loves the neighbourhood of the sea, and grows luxuriantly on the poorest soil; but, unlike that palm, it also thrives on the barren clay hills of the interior of many islands. It is the first fruit-bearing tree that grows out of the sand and shingle of newly-formed atolls. In the Line Islands, during frequent seasons of drought,* when the cocoanut palm ceases to bear fruit, the natives contrive to exist upon fish and the drupes of the never-failing screw-pine. The inner part of the drupe is fleshy and pleasantly sweet. Several tiny kernels, in extremely hard shells, fill up the outer part. On many of the Gilbert Islands preparations of the pandanus were presented to us, as the most valuable gifts they could bestow. First, the ripe, fleshy parts of the drupe, pounded into a flat cake, in appearance like a mass of pressed oakum; this we could not eat. Next came extremely thin paper-like stuff, consisting of the sugary juice of the fruit dried in the sun; this was very palatable. Lastly came a sort of sawdust, or fine nutritious particles out of the kernel and drupe dried; this too was very nice, but it would take a great deal of such food to satisfy the appetite. We gave the whole to the teacher. The long, tough leaves of the screw-pine furnish the best thatch in the world. It is usual to pare away the prickly edges and midrib with a knife. The leaves are "sewn" on reeds, or on the split adventitious roots of the parent tree. On some islands, until very lately, human rib-bones were employed for this purpose. It is to the process of "thatch-sewing" that the natives are indebted for the only word in their language *(tui)* for sewing, as their ancient garments were *pasted together, not sewn.* A house carefully covered with pandanus thatch will not need re-covering for ten or twelve years. The terminal buds and flowers of the pandanus are commonly eaten by the inhabitants of the low coral islets. Cattle love to browse upon the leaves. In the New Hebrides the petticoat worn by women and girls is prepared from the exposed roots of the pandanus by splitting and *chewing* them. The timber of the screw-pine, although poor, is used for house-building in all the low islands; and—on account of its being hollow—for piping in the high islands. The natives value the tree highly on account of the perfume yielded by the male inflorescence, used to scent cocoanut oil. The perfume is very powerful; to many Europeans it is very agreeable. The inner part of the drupe is cut off and threaded as necklaces, on account of the fragrance. When fresh and alternated with the deep-red, bell-shaped coverings of the seed of the *puka*, the effect is very fantastic. Native songs abound with references to this perfume *(Ara inano*, fragrant screw-pine). The octopus, doubtless attracted by the fragrance, climbs up the screw-pine to feast upon the flowers. Bats are very partial to the fruit. The interior of this tree is filled with loose fibres which soon decay. When very old—and it is believed to attain to a great age—beautiful walking-sticks, etc., may be made out of the hard external part.—(Signed) W. WYATT GILL, Raratonga.—*Leisure Hour.*

INSECTICIDES.

Next to artificial manures, of which we have from time to time published analyses, insecticides are probably offered in greatest number for the approval of gardeners. It is

* On one island rain has lately fallen, after a drought of *eight years.* It was painful to gaze upon those starving, heathen islanders, without the ability to relieve their wants. To save life many emigrated to distant islands, returning home, however, as soon as they heard that rain had fallen.

doubtful whether any of these insect slaughterers are more efficient in suitable cases than the general practice of fumigation. Nevertheless there are cases where fumigation is of no effect, or where its application is from various causes undesirable, and then the gardener has recourse to such tried friends as Gishurst Compound, or petroleum oil, or kerosene used in the proportion of a wineglassful of the oil to a gallon of water, in which soft-soap is stirred up so as to form an emulsion, and secure an equal mixture of the oil. To use this, constant stirring is necessary to secure the diffusion of the oil, and the liquid should then be applied to the plant through a fine rosed syringe or spray-producer. Constant stirring is necessary or the oil may kill the plant, as well as the scale insect. Prof. Riley recommends, as the result of many trials, the following emulsions:—Refined kerosene two parts, sour milk one part, or if milk cannot be obtained then condensed milk is employed, as in the following formula:—Kerosene, 1 gal., condensed milk 2 cans (1½ pint), and water 3 pints. Mix the condensed milk and the water before adding the oil. When the oil is added churn thoroughly till a sort of butter is produced. When required for use this butter should be diluted with twelve to sixteen times its bulk of water, so that the emulsion resembles milk, and it may in this state be used with a powerful syringe or, still better, force-pump, for the destruction of scale insects on Orange trees, Oleanders, Cactuses, &c. For other creatures, such as aphides, thrips, or red-spider, Pyrethrum powder applied as hereafter mentioned is more suitable. The Pyrethrum powder, known in commerce as Persian insect powder, is a veritable boon to suffering tourists, as many a traveller will acknowledge. The powder is made from, the dried flowers of Pyrethrum roseum, a hardy perennial, from which the now numerous double Pyrethrums of gardens originated. The plant is a native of the lower regions of the Caucasus Mountains, and is nowhere cultivated on a large scale. A nearly allied Dalmatian species, P. cinerarifolium, is used for similar purposes.

Both these plants might readily be cultivated here, though no doubt a hotter summer than we are generally blessed with is needed to develope the acrid oil, upon which the insecticide properties depend. The flower-heads should be gathered when fully expanded (but before the ripening of the seed), dried under cover, and finely pulverised; the powder, if not wanted for immediate use, should be preserved in tightly-closed vessels. When used as an insecticide it must be remembered that its effects are not permanent in the open air; if, for instance, it affects the insects on a particular plant, it has no effect upon those which may happen to alight on the plant half an hour after the application. Again, the powder is of no value unless it come in actual contact with the insect, and has no effect on the eggs or pupæ of the insect. In these particulars, says Prof. Riley (from whose paper in the annual report of the (American) State Entomologist for 1882 we extract these particulars), the Pyrethrum is less effectual than the arsenical poisons. On the other hand, the Pyrethrum is perfectly harmless to plants or to higher animals, and may thus be used without fear of untoward consequences. Under cover the Pyrethrum is naturally more effectual, so that its use in greenhouses or in domestic houses for the preservation of furs, or in the herbaria, or cabinets of the naturalist is very effectual. The ordinary mode of application is as a dry powder distributed by "dredging" the plant, or by the use of bellows, or of an elastic ball. This method of application is well known. Less familiar is the process of fumigation by its means; the powder burns freely, giving off much smoke, which suffices to kill or paralyse flies or mosquitos in a room, and is very efficacious in the case of furs, feathers, herbaria, or in greenhouses. An alcoholic extract may also be used, distributed by a spray-producer. But the simplest and most efficient plan, says Prof. Riley, is to dissolve (? suspend) the powder in water and use it in a fine syringe or spray-producer. Bentley's spray-producer will be well adapted for the purpose. The Pyrethrum water is most efficacious freshly made, and loses its qualities if kept.

Prof. Riley supports his conclusions by the evidence afforded by numerous trials made by himself or under his direction. It is pretty clear then that the gardener has in Pyrethrum powder, used as above described, a simple and efficient means of destroying many insects at a comparatively small cost. Indeed it is quite open to him to grow and prepare his own insecticide, and thus spare himself the expense of purchasing other not more effectual things at a relatively high price. To prevent disappointment, however, it must be added, that it is of no service in the case of hard-shelled insects, as beetles, scale insects, or hairy caterpillars; but for all kinds of aphis or greenfly it is spoken of as a specific, as also for flies and gnats. Whether it is fatal to wasps is not stated, but certainly it is hardly so to slugs, as most gardeners known to their cost.—*Gardeners' Chronicle.*

EUROPEAN AND NATIVE CULTIVATION ON THE PLAINS OF CEYLON:

NEW AND OLD PRODUCTS.

I've seen as much hill and lowcountry scenery as most people. I'd like to know where you will find a lovelier or a grander view than from my little new product estate bungalow, looking from the porch, covered with flowering creepers, towards Adam's Peak crowned with roseate-tipped clouds in the early morning, and bright with the reflected light of sunset in the evenings. Long groves of cacao, wide-spreading fields of dark green tea dotted about with the graceful areka palm are seen stretching away right and left, and a pretty rippling stream, close by, makes its pleasant way down to a cool shady dell, where may be seen as pretty a garden as in many an English homestead. It is well stocked with celery, carrots, onions, radishes, and lettuces, reminding one of the "old house and garden at home." There are flowers too, and there are grape-vines and orange trees and pines, and, in fact, most of the fruits of the country in abundance. Opposite the porch, beneath a clump of shady trees is a neat little aviary, well stocked with birds of song and plumage; pigeons abound and feed from a stranger's hand; all about us in short tells as pleasant a tale of Ceylon rural life as need be wished for. The air is ever fresh, bright, and invigorating, for it comes over cool green glades and heavy jungle in which the sun but rarely penetrates, and in the early hours of morning, when the wind descends upon us from the lofty ranges of the Peak, it feels quite spring-like, and reminds one of the air in Devonshire.

There is an excellent cart road from the railway, made with village labour at a trifling cost, for the people, knowing well how much it would help them in the transport of their few products to a market. Anyone who will come amongst these poor creatures and give them the smallest amount of work to place food within their reach, will earn their lasting gratitude. Too gladly they give their labour, and had they but the tools and the seeds; how cheerfully they would plant and sow and reap. I have done what was in my power by example, by draining, opening, trenching and planting with yams a rather large stretch of some unprofitable swamp on which from the earliest time an uncertain crop of poor sickly paddy was raised, a tenth of which was pounced upon by the village Arachchi on behalf of our Sovereign Lady the Queen. I brought together some of the villagers, and placed them on the work that they might profit by example. A wide and tolerably deep drain was cut midway through it, from end to end. Into this were opened cross-drains, smaller and covered over by slabs of stone. Then when the ooze water had made its way out, and the land began to dry and crack, the villagers were set to cut up the thick heavy turf, and stack it for drying, whilst the soil below was turned over mamotie-deep and allowed to remain so for a month. Then the dried turf converted into peat was burnt, and the ashes and burnt clay scattered over the face of the land and finally dug into it. At the end of three months the whole aspect, the entire nature of the place, was changed. It was no longer a pestifeous ugly swamp, but a pleasant field, on one portion of which a number of yams have been planted and are doing remarkably well, looking as strong and healthy as though on the best land in the province. From one small plot of this ground, reclaimed some time ago, the produce in yams has been equal to a return of R200 the acre, and this without any application of manure.

Now there is nothing in this proceeding that may not be adopted by any of the villagers about, and I have no doubt with tools they will follow the example thus set them. There are very few villages that have not an unprofitable

swamp, and what easier than to drain, pave, burn, and dig. These are the simple things in agriculture which should be taught to the people. Such improvements are comprehensible and tangible, and come home to the simplest understanding. What the poor of the rural districts require are instruction in the form of example, and tools with which to imitate. I have walked through many lowcountry villages, and have talked with the villagers, but very rarely have seen anything more formidable in the form of tools than catties. Often have I pointed out to the villagers how easy it would be to convert a dry sterile piece of their holding, that they had nothing from for a generation, into a garden plot, but the answer always was—"no tools, no seed." How some of these poor people manage to keep body and soul together is a marvel, but now that new products are making their way here, employment will be found for many, especially for women and children in tea plucking and rolling, but the tea about here is in its early stage, and so the employment is at present rather fleeting. But soon tea-houses will be erected, and there will be life and bustle and industry that will bring comfort to many a native homestead in the Plains. I find the villagers, men, women, and children thoroughly grateful for any little help given to them, although it is little enough one can do for all of them.—"Ceylon Times."

COCONUT GROWING.

TO THE EDITOR OF THE "QUEENSLANDER."

SIR,—Although the cultivation of a variety of tropical products has been, it is said, engaging the attention of planters in Northern Queensland, it is singular that coconut planting has not attracted more notice than it appears to have done. There is no doubt that the climate and soil on the coast of Northern Queensland is favourable to the growth of the coconut tree, and coconut planting gives a fair return when attended to in a systematic manner. To begin with, there is a good demand for coconut oil in the London market, and out of the husk good cordage is manufactured; in fact, scarcely any other is used in the East. A fair sort of sugar, or, as it is called "jaggery," is made from the sap. And perhaps it is not generally known that the sap of the tree, which goes by the name of "toddy," makes a very refreshing drink, and is credited with possessing great medicinal properties. From the toddy is also distilled the famous arrack of Ceylon, which, when pure, and improved by age, is equal to the best whisky, and is far superior to most of the brandy and rum sold in these colonies, and which often goes by the name of "chain lightning" and "fighting rum." As a proof of the wholesomeness of Ceylon arrack, it is used in India in the Government hospitals, and used to be served out to the troops. In Ceylon the Government has a good amount of revenue by the sale of the arrack rents every year, and the liquor is sold by the retailers at the price fixed by law—of 4s. 8d. per gallon. Among the planters and other European residents of Ceylon and India, to use the liquor, though palatable and good, is not considered the "right thing," not because it is not liked, but it is considered degrading to the position of the European to drink that which is sold in all the native taverns or canteens, and is chiefly drunk by soldiers, sailors, and the natives themselves; although there was a Governor once in the island, Sir Robert Wilmot Haughton,* who had such a predilection for it that he preferred it to any other spirituous liquor, and afterwards through this, it took the name of "Haughton," and sometimes goes by that name still. However, leaving aside the manufacture of arrack, which is not engaged in by Europeans, and the prejudice entertained against that liquor by them, they engage in coconut planting because it is profitable. With regard to the medicinal properties of the sap or "toddy," it is related that when the Portuguese first went to Colicut, or Calicut, there was among the crew of one of their vessels a man who had contracted a contagious disease of a nature that need not be explained here; but he was so bad that none of his shipmates liked to go near him, a portion of the roof of his mouth having completely rotted away. He was given up by the ship's medical man as incurable. But a native doctor having come on board and seen the sufferer undertook to cure him; and in a short time he did so to the astonishment of all on board, and the doctor in particular. The cure is said to have been effected by simply giving the patient quantities of toddy to drink. The truth of this was vouched for by a missionary who was on board the vessel at the time, and who, in writing an account of the voyage, mentioned this circumstance. However, the efficacy of the use of arrack in cases of cholera has been believed in in India from a very remote date by the natives. Though coconut planting may not bring in returns so soon—nor perhaps so great—as coffee-planting, it certainly is not attended with the risk, nor does it require the outlay that coffee does—that is, if coffee planting is carried on in the way it is in Ceylon. And, as far as coffee planting is concerned, it will also be found by those who try the experiment (with the exception of small patches that can be watered by hand) that Northern Queensland has neither the climate nor other conditions necessary to ensure coffee-planting on an extensive scale ever becoming a profitable pursuit. In the first place, *Coffea Arabica* requires certain elevations, even when in the proper latitude. Northern Queensland is in the proper situation as far as latitude is in question; and, provided also that land of suitable elevation is to be found, the country is subject to severe droughts extending over such long intervals, that the coffee-berry, the development of which depends wholly on rain at suitable intervals, never comes to maturity, or is such as to be totally valueless as a staple of commerce. The above remarks do not apply to Liberian coffee. The coconut, unlike the coffee tree, requires no elevation, and is not nearly the trouble or expense. About the greatest trouble experienced in Ceylon in coconut planting is the protection of the young plants from the ravages of the porcupine, and which is done by digging deep trenches or drains around them. It is true that coconut planters were sometimes plagued by a beetle which used to pierce the young nut, and thus destroy it. But this was only in certain localities; and planters in Northern Queensland, I believe, have not got the porcupine," nor are they likely to be troubled with the insect abovenamed.—I am, sir, &c., J. BUCKLEY, Brisbane Valley Railway.—*Queenslander.*

[Much of the foregoing with reference to the coconut is well worthy of the attention of Northern coast residents. Sandy country near the sea suits it admirably, and in the great country for coconuts—Ceylon—one cooly per acre furnishes all the labour required. But the remarks *re Coffea Arabica* are scarcely in accordance with the experience of those who have grown it, this variety having been fairly successful wherever properly tried in the North. Prolonged droughts in the coast districts of Northern Queensland, too, are rare.—ED. *Q.*]

* Horton.—ED.

DEMERARA CRYSTALS.

The colony of British Guiana may be fitly described as, at the present, a vast manufactory of "Demerara Crystals." These sugar "crystals" fetch "fancy" prices in the European market, they are held in high esteem in English households, and there is little marvel in this to one who has visited the home of their production. It is probable that the "chemistry of common life" has no more distinct illustration of success. The whole system of production in scientific to the last degree; and when we remember that the system results in an annual output valued, even at low prices, at not less than £2,400,000, we see we are dealing with a system of very practical interest to consumers as well as to producers of "sugar." Moreover, there is already £2,000,000 worth of machinery at work in the colony; the annual importation of English manufactured goods now exceeds £1,000,000, and the total tonnage leaving the port already exceeds 200,000 tons. This community, it will be seen, is a great customer for our home producers, and the sole present basis of its property is sugar, and that chiefly in the form of Demerara crystals.

The sugar planters out here have taken their cue from the refiners in England, and have with vigor joined the loud throng who with superstitious unity of feeling attribute every evil incident to sugar to the influence of the bounties. The mysterious term has been erected into a scapegoat, and made to carry all the blame which is

in reality due to endless other influences. But even trade depressions, bad seasons, and over-stocking of markets have not always so much effect as new developments of manufacture; and this is a class of influence altogether ignored. Demerara crystals constitute one signal and important instance of this class. The planters here have devised a system which supplies the English market with a raw sugar fit to go into English consumption without further refining. We have thus a sugar under the very cheapest of conditions, and directly competing on the very breakfast-table with other sugars the result of extensive sugar growing operations in one part of the world, and extensive sugar refining operations in another part of the world. The English makers of this particular class of refined sugar—of crystals—whether in Bristol or in Glasgow, will, by degrees, accumulate experience sufficient enough to accept this fact, and no longer go wailing the country over that French sugar bounties alone have ruined their business.

But if Demerara crystals are thus indictable for influences hitherto attributable solely to bounties, these crystals are acting most prejudicially on these obnoxious bounties themselves. It is not merely a matter of supplying sugar at the cheapest scientific cost, but a system is now being introduced here, the "Weinrich" system, which puts in the market what is practically a Loaf-sugar. And, as we are told that loaf sugar has almost entirely gone out in England, this is an item of news of significant interest to our bounty-fed continental competitors. There is thus much reason for detailing the present condition and the prospects of the sugar industry in this thriving colony.

British Guiana is a business-like colony. Others, envious of its success, term it the "mud-colony." But this "mud" is the staple basis of its high prosperity. It is reported to be "an alluvial deposit composed chiefly of blue clay, impregnated with submarine salt and rich in decomposed vegetable matter." This mud extends far; the great majority of the 70,000 acres planted with sugar cane are actually below the level of the sea, fenced round and about with sea-walls and dams, and yielding an area of soil, all alluvial, for 100 feet in depth, that is practically inexhaustible, and yet most easily worked. The area, so utilised, is comparatively a mere strip along the coast, reaching never more than a few miles inland, to the belt of "tropical forest" which interposes the barrier of a soil that is nothing else but a loose piling up of vegetable *debris*, nowhere sufficiently compressed to be even good peat. But beyond this, again, when higher land is reached up the rivers, there are reports of experimental yields of enormous growth; of sugar-cane attaining a circumstance of seven inches. Only to utilise this alluvial area considerable capital has been needed; £80,000 for a sea-wall on one single estate was considered a mere incidental expense. But this habitual investing of capital has, in the course of years, produced an artificial sugar-growing area that gives facilities for the production of sugar that must strike dismay into the hearts of Beet sugar-growers.

It will be valuable briefly to point out the advantages enjoyed here in the different processes by which sugar-cane is transformed into sugar fit for the table. First, then, in regard to the growing of the cane itself, it is found that the variety of cane has far less to do with the percentage of sugar yielded than the soil and mode of tillage, combined with the season. The question of water is being here set to rights by an elaborate system of drainage, which, as it becomes realised, so lessens considerably the cost of cultivation. Even now fresh water is always to be had in sufficient quantities. As a sign of the progress and improvement in this direction, it may be well to notice that, by skilful levelling, natural drainage has been in great measure to supersede pumping—a task of no little expense where neither coal nor labor is cheap. Most estates lie between the high and the low water level, and this substitution has been highly feasible. It has been estimated that on some estates this substitution of natural for artificial drainage has reduced the cost of producing a ton of sugar by no less than £2. But, besides this, these irrigation schemes have aided in developing the system of water carriage, which already forms the main feature of every estate in this colony. Small canals regularly intersect the cane fields, and on these ply light barges towed by mules.

The question of tillage has been gone into with corresponding vigor. Plough and spade work and every dreamt-of system of drainage or ridging have had due attention paid to them. The general result has been a very heavy crop of crystallisable sugar per acre, which is transferred cheaply and readily by this water carriage to the works; and nearly all these works are connected by further irrigation outlets with the shipping in the ports.

The works themselves are of remarkable magnitude and finish. The plant and machinery actually in work boast a present value for the whole colony of not less than £2,000,000, and the various processes fall nothing short of the most advanced discoveries of the day—even to the application of the electric light, should night work be desirable. After this scientific cultivation and scientific hauling there remain those great divisions of process before sugar in the cane becomes sugar on the table, and in each of these British Guiana exhibits a height of science rarely attained elsewhere.

Considerable improvement has of late taken place in the extracting of sugar from the cane. In 100 parts of cane there are, on the average, 17 parts of saccharine matter. By the common method of extracting this the cane is crushed between heavy rollers, and most of the saccharine matter squeezed out in a juice or syrup. This was long thought the only possible process, thought it was well known that eight to ten of these original parts of saccharine matter remained a fixture in the cane. West Indian planters have to thank the much-abused bounties for discovering a remedy for this evil. The excise tax on beet sugar in Austria was levied on the amount of sugar a ton of beet could yield by crushing; this was, say, five parts in every hundred. The drawback system paid to the refiner the amount of this excise tax on every five parts per hundred he exported. He thus secured back the amount he had paid away, but he found enormous profits in the substitution of other methods which obtained from the beet more parts of sugar than the five he could get by crushing. He found that if, instead of crushing and squeezing, he simply sliced his beet and allowed it to become well steeped in warm water, he extracted from the beet 12 of the 13 parts of saccharine matter in each 100. Cane-growers have not yet adopted generally any actual "diffusion" process, the only difficulty that yet retards such action being the difficulty of cutting up the cane. But they have adopted in Demerara an intermediate process, known as "maceration," by which the cane, after one severe crushing, is passed over steam, gradually increasing to a heat of 180 deg. Fahrenheit. It is then crushed again, and, in the end, it has yielded up in the various processes 15, at least of the 17 parts of saccharine matter it originally contained. The exact results of this process are, however, in debate, and more important even than these is the question of pounds, shillings, and pence. Does this extra yield of a few parts of sugar repay the extra expenditure in plant, machinery, fuel, labor, and time? It is also asserted that the cane-refuse, after this double crushing, is greatly deteriorated in value as fuel; and in many works this refuse or megass, is the sole fuel used in boiling the sugar.

It is, however, not at all improbable that the diffusion process, pure and simple, may in the future supersede both the crushing and the "maceration" processes. The only difficulty is the dividing the cane into layers sufficiently thin for each sugar-holding all to come into open contact with the water. This being accomplished, the cane is automatically soaked in sixteen fresh liquors for ten minutes, each soaking in water gradually rising to a temperature of 180 deg. Fahrenheit. The machinery necessary is not expensive, no steam power is required and the proportional amount of labor is largely reduced, —a fact of the first importance in the West Indies. There is no doubt that if diffusion can be applied to cane more generally, it will again considerably lower the cost of production, even to the extent of one-third, if we are to believe that it would free for clarifying sixteen of the seventeen parts of saccharine matter, only eight or nine of which are obtained by the crushing process.

The question of labor—the greatest of questions in the West Indian colonies—has been settled more or less satis-

factorily in British Guiana by the instrumentality of a vigorous immigaration system. This has not only supplied numbers, but variety; and the consequence is that, with nationality to set off against another, not only is there a potential incentive to all to work, but there comes to exist a considerable natural guarantee against riot and labor troubles of all sorts. With all these advantages—of tillage, of labor, and of invested capital—the planters here have thus been enabled to produce sugar on a system secure against competition elsewhere. We have spoken of the merits of their method of growing cane and of extracting the sugar; they are equally successful in the converting of this rude saccharine matter into portable raw sugar; and, further, in refining this again into edible sugar. The ordinary boiling-down process is finished off by means of the vacuum pan, and much of the sugar so finished passes through the centrifugal machine, and reaches the home market to be put directly on the table of the consumer, to the great consternation of many of our English refiners.

In British Guiana the cost of producing sugar—inclusive, that is, of the capital invested in machinery, in land, in stores, and of the money expended in labor, superintendence, and so forth—varies, of course, with the particular kind of sugar turned out in the works. There are common-process raw sugars that fetch £20 in the English market, and there are the best Demerara Crystals, the home price of which often approaches £30 the ton. The cost of production in the colony varies, with the kind of sugar produced, from £8 up to £16 the ton. The cost of transference to the English market need never exceed £4. It is certain that beet growers can never destroy the facilities which nature here offers for the production of sugar. There are, of course, great risks here, and the capital invested is great, and some account has to be taken of a dim consciousness that, as with cotton and coffee—which were years ago at successive periods the great articles of export—so the day may come when cane sugar shall no longer be exported at a profit, and all capital fixed in machinery and so forth will be sacrificed altogether. But, nevertheless, for the present, with its large expenditure, its large output, and large profits, the industry of sugar-growing in British Guiana has, it would seem, attained to a scientific thoroughness which will enable it to outlast any temperary obstacles or competition whatever.—*Produce Market's Review.*

COFFEE CULTIVATION IN BERBICE, 50 YEARS AGO.

BY ALEXANDER WINTER.

Although there is no coffee estate now in Berbice, and has not been for many years past, yet coffee cultivation was at one time a very important industry here, even more so than sugar. At the time of the junction of the colony of Berbice with those of Demerara and Essequibo, forming the united colony of British Guiana, which was in 1831, there were in full operation in Berbice 31 sugar estates, 40 coffee estates, and 8 cotton estates. Of the 40 coffee estates, 17 were situated on the right bank of the Berbice river, 17 on the left bank, and 6 in Canje.

These were owned partly by resident proprietors, living on their own estates such as the late Wolfart Katz, Esquire, said to have been the most extensive *resident* proprietor in the West Indies,* partly by English merchants residing in London or Liverpool, and partly by Dutch merchants residing in Amsterdam and represented by Dutch planters living in Berbice

The history of some of these estates is rather curious. Several of them were owned by the once well-known Paul Benfield, a large capitalist, the Rothchild of his day, who negotiated loans for Governments, and had advanced large sums to the French Government in the time of the Bourbons. When France became a Republic after the revolution of '92, these claims were repudiated; and Paul Benfield is said to have died a pauper! At the restoration of the Monarchy however, after the battle of Waterloo, Benfield's claim was acknowledged and honestly paid with interest, and his family then became very wealthy. Two of the heiresses married members of the Berkeley family, who thus became connected with this colony as owners of what were called the "Benfield's estate." These consisted of plantations *Edinburgh, Glasgow, Welgeleyen, Herstelling, New Welgeleyen, Belmont, Union. Monchoisi, Zeelught and Edderton,*—in all 6,655 acres. They were not very thriving estates, and Grantley Berkeley, one of the parties interested, used sometimes to get up in Parliament and asked the Colonial Minister how it was, "that he got such small returns from his estates in the West Indies." These estates have all now been out of cultivation for many years; and the land has been sold to villagers!

What were called the "Dutch estates" were mostly in the possession of large mercantile house in Amsterdam such as Waterloo & Co., Charbon and Zoen, and Westerick and Poole, who held the titles of the estates in their own names and administered them through the agency of their attorneys in the colony. They also shipped all the stores and supplies for the estates in their own vessels, which also carried home the crops, which were kept on hand till one of the Dutch ships arrived; for the crops were bound to be shipped to Holland, and in Dutch bottoms. These Dutch ships were very awkward clumsy looking vessels, high at the bow and stern and low in the middle. They were not very fast sailors, but very safe.

Although the merchants of Amsterdam had the entire charge of the Dutch coffee estates in their hands, they were not really the owners; for these were owned in shares which were transferable and could be bought and sold on the exchange, like shares in any company. This practice is reviving in the colony, several large estates in Demerara being now owned in transferable share on the old system. This has probably been adopted in consequence of the peculiar and inconvenient Dutch law of inheritance.

These estates were conducted on a different system from the English estates. The managers received very small money salaries, but it was made up to them in other ways. For instance, their houses were furnished for them, and they were allowed a small share of the plantains, rice, salt-fish, tobacco, &c., sent to the estates for the people; then they could help themselves to the osnaburges, salemporas drill, &c., shipped from Holland for the same purpose, and have them made up into clothing by the house servants; so that they had very little to buy, and were very comfortably off; besides which, the Dutch ships when they came in always brought the resident managers and attorneys supplies of schiedam, claret, liqueurs and other good things for the table. On all of these the merchants in Amsterdam had their commission.

All the coffee estates were pleasant places to visit. The managers generally had a good deal of leisure time on their hands. They kept nice gardens, and had abundance of vegetables and fruit to spare; the hedges were neatly trimmed; and altogether these surroundings were very picturesque and attractive.

The cultivation of the coffee was a kind of gardening, and consisted of weeding between the coffee-bushes, and trimming the old branches so as to promote the growth of new wood, from which alone fruit was to be expected. The coffee was planted under the shades of tall trees called in Berbice Sand-Ookers, in Demerara Oroneque-trees, and botanically *erythrina crystagalli.*

Coffee, at the best is a very uncertain crop. It requires peculiar weather; a spell of dry weather to check the growth followed by copious rains to bring out the blossom. If instead of this there were continual showers when the trees were "working," as it was called, the result was a development of leaf, instead of flower buds; and there was no crop.

Were all things favourable, and there were signs of a good blossom, the news soon spread throughout the colony, and all parties connected with coffee estates were astir, and eager to go and witness the "coffee blossom." It was best seen in the early morning, before the sun was high, and you had to start at a very early hour. Some enthusiastic planters

*Mr. Katz lived in a fine mansion on his Plantation Vryheid, a coffee estate near New Amsterdam; besides which he was sole owner of Plantations Philadelphia, Gebroeders, S'Gravinhague, Cotton Tree, and Belair or Number six, on all of which there were large gangs of negros. Although the compensation allowed by Government at the time of emancipation, was only 8s. in the £ on the appraised value of the property taken, Katz's share of this was over £63,500 sterling.

would take their hammocks and sleep aback, in order to see the blossom to advantage, and make an estimate of the probable extent of crop.

The large estates had some five or six hundred acres in coffee, divided into fields of ten acres each, separated by intervals called "alleys." These being mostly planted with fruit trees were called fruit-alleys. Each field had the number of trees it contained painted on a board at one corner of the field; so that, to judge the extent of the "blossom," you had to decide what was the average to be expected from each tree, and then multiply it by the number of trees, modifying it by circumstances, some fields having more young trees than others some more "water sprouts" from neglect in pruning, some being injured from neglect in weeding. It required considerable experience and practice to make a correct estimate. If the blossom was a fine one, you might see people driving into town in triumph waving branches of coffee trees, white with the jasmine-like flowers.

But there was still uncertainty; the blossom did not always "set" as it was termed, or form fruit; or from some cause, the young fruit would drop, and there would be great disappointment.

If all went well, and the crop began to ripen, the busy time of the coffee estate commenced. All hands were sent aback to pick coffee and everybody that could be mustered was employed in getting in the harvest before it fell from the trees. Horses were turned out to graze, that the grooms might pick coffee instead of cutting grass: managers and attorneys had to diminish the number of their attendants as much as possible, and every effort was made to secure the crop, the reward of all their soil.

There was much competition among the neighbouring estates, as to which should make the largest crop. As soon as 100,000 lb. was gathered in, a flag was hoisted at the top of the logie, and great were the effort to be the first to "hoist the flag." The people, too, shared the excitement and it was a cheerful sight of an afternoon, to witness the return of the pickers from aback; bateau after bateau would be seen racing home in the canal, each loaded with baskets of fresh picked coffee, which looked like red gooseberries.

On reaching the buildings, the coffee was carried up into the loft over the pulping-mill. Here it was measured. The coffee, as it was brought in, was poured into a square box which held as much green coffee as would yield 14lb. of clean coffee when divested of its pulp. A tally of the number of boxes was kept by an overseer and each person bringing in a boxful received a ticket.

From this upper floor the coffee was sent down a spout or shoot to the mill, where it was divested of its outer husk or pulp, which fell in one place, while the beans fell in another. The pulp was carried away and thrown in a heap where it soon fermented, and became most offensive to the neighbourhood far worse than the "lees nuisance". The beans, divested of the pulp, fell into a brick gutter, sloping down to the wash pit. This was a square brick cistern, about 5 feet deep, into which water flowed in at one end and out at the other. Here the coffee was washed, being hauled backwards and forwards by a kind of wooden rake. This washing cleaned the beans from the slimy juice adhering to them, and they were then taken out and spread over the "droogheric," a raised and tiled pavement sometimes called the "barbacot" or "plankier" where they were dried in the sun, and were then carried up to the logie, to be stored till the picking of the crop was finished. There were generally two crops in a year.

If the crop was large, great care had to be taken that the coffee in the logie did not get heated, and thus spoilt. To prevent this, it was spread as thinly as possible and constantly turned by wooden shovels day and night. Large as the coffee logies were—many of them over 100 feet long—when the coffee was plentiful there was danger of its getting heated, and extra buildings had to be used to house some of the crop. Occasionally managers and attorneys had to submit to having some of their rooms used for this purpose.

When the picking was over, the crop had to be prepared for shipment, which was a somewhat tedious process, requiring a good deal of care and attention. It had first to be husked and deprived of the "parchment skin" which surrounded each bean. For this purpose it was first spread out on the droogheric and dried in the sun till it became quite hot, and the outer skin crisp and brittle. It was then taken to the "stamping-mill" and thrown into circular trough about 3 feet deep and a foot wide, and subjected to the pressure of two heavy wooden rollers, a foot wide, six feet in diameter which were kept revolving by mules. This process broke the crisp outer skin, which was blown away by the winnowing machine like chaff, leaving the coffee quite clean and fit for use. It had however to undergo further manipulation, as the different qualities had to be sorted and shipped separately. This took a good deal of time, as every single bean had to be separated by hand. This was done by women who sat down on the floor of the logie in long lines, each having her allotted task before her in a sieve. The coffee was carefully hand-picked, the good beans being put into one calabash, those broken into another, and the inferior discoloured beans, (the effect of "heating") into a third calabash to be thrown away.

The "broken coffee" was as good as the "whole" in quality, but inferior in appearance, and was called "triage" by the London brokers, and sold at a lower price. There was always a proportion of pearl coffee in every crop, and this was considered the best of all. When a berry instead of having two beans, had only one, it took a rounded form instead of being flat on one side, as usual; this was the so-called pearl-coffee. If the proportion of pearl-coffee was considerable, it was separated from the rest and shipped by itself. It sold high in the London market, fetching 120/ per cwt. when other coffee sold for 80/ or 85/. But the quantity of pearl-coffee shipped was not great.

The coffee when cleaned and prepared for shipment was put away in a large air-tight compartment, called the coffee chest, which was of sufficient dimensions to hold the whole crop; for this had to be kept on hand until the ship that was to take it arrived. These coffee-chests were built of dark wood and were kept carefully polished; for the planters were very proud of them. They were made perfectly air-tight, not only at the sides but at the top also. When the coffee was wanted for shipment it was taken out of the chest and put into tierces or bags.

Coffee was more or less injured on the passage home, by the steam from the sugar on board, and it was desirable to ship it, if possible, in a vessel loaded entirely with coffee, or at least, having no sugar on board. A small vessel came here once from Jersey loaded entirely with potatoes in bulk; these were readily disposed of, and the ship loaded home with coffee.

The freight of coffee was higher than sugar, it being lighter; when the freight of sugar was 3/ per cwt., coffee paid 4/.

Berbice coffee ranked high in the market and was bought to mix with Jamaica coffee, which being grown on the mountains, was more delicate in flavour than that from Berbice but not nearly so strong.

That particular quality is still called "Berbice coffee" in the shops in London, though none has been shipped from Berbice for twenty or thirty years.

The cessation of the coffee cultivation has been a great social loss to Berbice, as reducing the number of the educated class. Each estate had not only a manager, but by law was obliged to have a white overseer for every hundred negroes. But it was impossible to continue the cultivation under the free system without loss. This the Dutchmen very soon discovered, and they sold their estates and cleared out to a man. The free system did not suit their ideas at all, any more than it does that of their countrymen, the Boers, in South Africa.

There were several reasons for this, but the principal one was, that the negroes, when entirely free would not pick the crop. At first they would do a little. For instance a woman would go aback and bring in a basket of coffee about 12 o'clock, for which she got a guilder. Then urged to go and pick a second or third basket, which could easily be done, and was done under the coercive system, the answer was "No. I am not inclined to work any more to-day. I have earned my guilder and am satisfied." The consequence was that half the crop fell from the trees and was lost; for, when once ripe, the berry does not remain long on the trees. When the negroes bought land, and lived in their own houses, the coffee estates got none of their labour, for it all went to the sugar estates, where they preferred going, when disposed to work for money wages. They showed a

marked preference for working on the sugar estates. This really was the cause of coffee cultivation being abandoned. It was not so much a question of price, but simply the want of labour. The only supply of labour in the country was that of the emancipated negroes; and that was withheld. Besides which the estates lost their market plantains. Formerly the coffee estates not only fed their own gangs with their plantains, but had contracts with the sugar-estates to supply them; and so they were sure of a sale for their plantains. After freedom this market was lost, and there was nothing to meet the current expenses of coffee cultivation; and very soon the negroes themselves became growers of plantains. So there was nothing for it but to give up and go; the buildings were sold off as old materials, the land was either disposed of, in lots to villagers, or taken over by some neighbouring sugar-estate. And thus coffee cultivation in Berbice, once such a thriving industry, became a tradition of the past!—*Royal Gazette.*

A NEW VARIETY of aniseed has lately appeared in the market, imported from Chili. Eighty-six bags of this variety were offered at the London drug sales this month, but fetched a low price, being small and not so free from stalks, etc., as European aniseed.—*Pharmaceutical Journal.*

FRUIT TREES AND WEEDS.—The *American Agriculturist* is as much opposed to weeds as agriculturists all over the world are. But, in dealing with orchard culture, it recommends a subsidiary crop in the shape of red clover. But this is that the pigs may be turned in to feed and fatten and *manure the soil*:—It is strange that more is often expected of the area appropriated to the orchard than of any other land upon the farm. It is expected to produce two crops each year, and to do so without manure. The space between the rows is occupied by some crop, or the whole surface is in grass, and made to afford a crop of hay as well as a crop of fruit. The many "run-down" orchards in all of the older States testify to the prevalence of this custom. In the renovation of an old orchard, the first step should be *to give the trees the whole of the soil*, and the next, to improve the soil, in order to nourish the trees. There is but one crop which should share the soil with the trees —that is, the pork crop! As a means of keeping a productive orchard in good condition, and as a method of bringing up an unproductive or run-down one, give it a generous manuring, and sow red clover. It would have been better had the manuring and plowing been done last fall, but better do it now than to wait. When the clover is well established, the pigs may be pastured upon it, but no other animals should be allowed in the orchard.

CEARA RUBBERS IN CEYLON.—Ceara Rubber grows very well in Ballangoda, where I know of its having been cultivated for some time past, but on only a small, and, I might say, an experimental scale. There are also several trees on an estate in Bambara Cotowa. Most of the trees are at an elevation of from 2,000, to 2,500 feet; and some of which I have personal experience, as I planted them in 1880, are looking remarkably healthy, though irregular in point of height. The best out of the number I planted is about 20 feet high, and eight inches in diameter at the base. I operated on this tree a few days ago, and found that the milk, though firm and thick, did not appear to be present in any very large quantity. Last year the quantity of milk was more, though of a very watery consistency, that at the time I believed to be due to extreme wet, but from my last experience, this view is not supported by the facts of the case. The Ceara Rubber comes into flower during the first, and seemingly every succeeding year; but I learn that the first year's seed is objected to for planting purposes. Shelter from extreme wind is very necessary for this tree, for the stem is easily broken by a strong gust, which, though not fatal to the life of the plant, throws it back very considerably, till replaced by a new shoot or "sucker." I believe it is said that nothing will grow under Ceara Rubber, but this is quite contrary to my own experience, for I have found that weeds, as well as larger plants, thrive perfectly under the influence of their lactiferous companions. The Mozambique variety has been tried on one estate in the district, but its growth—about 6 inches in a year—is very much against it; but it is very possible that the climate is unsuitable, or we are ignorant as to the locality and altitude best adapted to the successful cultivation of this product.—"Ceylon Times."

A GOOD WORD FOR OATMEAL.—Among the people who use it, and in the analysis of the chemist, it stands confessed as of the most nutritious and economical foods that can be used. The Scotch people are living examples of what oatmeal will do to make an athletic race with plenty of brain, bone, and muscle. The Scotchman's average daily ration is 2½ lb. of oatmeal and a pint of milk. On this he thrives and performs the labor of the farm. Analysis shows that oatmeal is very rich in nitrogenous matter, and comes much nearer wheat flour in nutritive value, than is generally supposed. The following table shows their comparative value.

	Oatmeal.	*Wheat-flour.*
Nitrogenous matter	12·16	10·8
Carbo-hydrates	63·08	70·5
Fatty matter	5·06	2·0
Saline matter	3·00	——
Mineral matter	——	1·7
Water	15·0	15·0

There can be no doubt that oatmeal cooked in its various forms might be added to the list of our dishes in the farming districts with great advantage. It is one of the best sustainers of muscle in the list of human foods.—*American Agriculturist.*

CLAY IN A NEW RÔLE.—All fertile soils are largely composed of clay. The best lands for permanent cultivation are heavy clays well drained and pulverized. Their fineness of grain allows the free penetration of the exceedingly small feeding roots and root hairs of plants, and by capillary attraction they bring up moisture from below to withstand drouths. A very sandy soil is greatly improved by mixing clay with it, to form a loam. In its pure state, and in combination, clay constitutes the largest portion of the crust of the earth. In the form of bricks it is used in the construction of a large percentage of human dwellings public buildings, and mercantile and manufacturing establishments. Chemistry makes many interesting and useful revelations. It shows, for example, that every 58½ ounces of dry common salt is made up of 23 ounces of a metal much like silver in appearance, and 35½ ounces of a yellowish gas (chlorine), so acrid, that a pint of it mixed with the air of a room produces great irritation of the lungs, if not suffocation. It was discovered only 56 years ago that every 51½ ounces of pure dry clay is made up of 24 ounces of oxygen (which forms four-fifths of the bulk of air and fifteen-sixteenths of the weight of water), and about 27½ ounces of a most important metal called *Aluminum.* This clay metal, if it can be obtained pure in sufficient quantity, is more valuable for almost all uses than any other known metal, except iron.—*American Agriculturist.*

CUPREA BARK.—A few months since Dr. Hesse stated (*Pharm. Journ.* [3], xii., 517) that in a peculiar thin kind of cuprea bark, of a much paler colour than the ordinary bark of the *Remijia pedunculata*, he had found, in addition to cinchonine and a new alkaloid, a large quantity of aricine and cusconine. This "new alkaloid" he now believes (*Berichte*, xvi., 58) to be identical with the "hydrocinchonine" of Caventou and Willm, and the alkaloids he then regarded as aricine and cusconine, he now finds to consist of several new bodies. At present Dr. Hesse has separated an alkaloid which he calls "concusconine," as standing in the same relation to cusconine as quinidine to quinine; another which he has named "concusconidine," analogous to cusconidine, and a third, somewhat resembling aricine, which he believes may eventually prove to be identical with Arnaud's cinchonamine. As Dr. Hesse is extracting the alkaloids from about 100 kilos of this bark, there is a possibility of the discovery of other alkaloids and an elucidation of the question as to the identity of cinchonamine. Diconchinine (diquinidine) and a small quantity of cincholine are also separable from the amorphous bases of cuprea bark, and more conveniently that when dealing with cinchona bark. In these days of unbelief it is satisfactory to learn (*Berichte*, xvi. 60) that Dr. Hesse has confirmed the independent statements of three sets of observers as to the existence of a peculiar alkaloid in cuprea bark,—"homoquinine," "ultraquinine" or "cupreine,"—by an examination of a portion of the alkaloid obtained by Messrs. Paul and Cownley in their investigation. He states moreover that, although working with quinine and quinidine of absolute purity and prepared from cuprea bark, he has been unable to obtain the compound of quinine and quinidine which Messrs. C. H. Wood and Barrett stated they had prepared.—*Pharmaceutical Journal.*

CEYLON TIMBERS FOR TEA BOXES.

Since writing on this subject, we have looked over Mr. W. FERGUSON'S notes on MENDIS'S list of Ceylon timber trees, singling out those described as inferior for general purposes, from their lightness and want of fibre or great strength, as probably the most likely to be sufficiently useful without being too costly. We fear *luna-madilla* is too good, but the specimen box of the much despised *hal* is certainly most encouraging. From what is said of the "*alubo*" "this is one of the largest trees of this order growing in Ceylon and common in the Western Province, but it is not a valuable timber though used for house-building,"—we should think it might answer? Also *bata-domba*, used for house-building and agricultural purposes? *Kadol*, one of the mangroves, "the timber of which is seldom used if any other can be had," might, like *hal*, when well seasoned, do for tea boxes? The *kattamba* or country almond is a ready and rapid grower and its light but durable wood might suit? Plantations of this tree could be quickly established. *Diya-para*, which is "seldom used except for common house-building," might answer for tea boxes. *Mandora* is, we fear too much in request for rafters and reepers in house-building. *Halamba*, though "scarcely deserving a place amongst the really useful timber trees of Ceylon" (written when tea boxes had not come to the front), might, when well seasoned, be good enough for carrying tea to London in, the tea being protected by lead? *Hora*, just because it shares with *hal* the position of being one of the "most despised of the timbers of Ceylon," may be cheap enough while good enough (if thoroughly seasoned) for tea boxes. The *kahata* is the tree with large oak-like leaves, so commonly scattered over the patanas of Ceylon up to 3,000 [5,000?] feet. As "its timber is in great request in Ceylon," it might be cheap enough to be used for tea chests, but perhaps the timber is too heavy: 50 lb. a cubic foot, when seasoned? *Kabella*, which grows up to 3,000 feet, and which, though "used for building purposes, is not considered valuable," might be good enough for tea boxes? The timber of *kiripalla* and that of all the Indian figs (bo, banyan, &c.) is described as nearly worthless, but some of these, well seasoned, might answer the purpose of the tea planter? *Lawulu* might suit, just because "the wood is used for common house-building, but is not valuable." What we want is cheap wood, but *sufficiently* good. The *mora*, the wood of which is used for common house-building but is not much in request, might answer? The *nelli* shares with the *kahata* the possession of the upland patanas, and, although in Ceylon its timber is not valued as it is in Madras, it might be good enough and of sufficient size for tea-boxes? Trees which will flourish on Ceylon patanas, resisting the action of periodical fires, ought surely to be valuable? *Ravana-idala*, which has a range from the coast to 7,000 feet, is "used for common house-building" and might answer for tea chests? *Ruk-attana*, with "its timber, white, light and used for coffins, packing cases, &c.," looks as promising as *hal* itself. Has it been tried for tea-boxes? *Telamba* we merely mention for the purpose of turning up our nose at its timber, which is said to be as fœtid as its flowers. If the smell can be dispelled (and it surely can?) the timber seems all that could be desired—"light, tough, easily worked and not liable to split or warp." The fœtid odour, it appears, becomes apparent only when the wood is bruised, which tea-boxes are certainly liable to be. *Wal-bomba*, properly *bomba*, is we find a *symplocos* (*S. spicata*), and, therefore, allied to, if it is not the very tree, the roots of which poison tea-bushes to death? It is common from the coast up to 7,000 feet. The wood is close in grain, light, very deficient in fibre and not durable: it is used for common house-building and firewood. This tree of wide range, if not high character, might, perhaps, answer well enough for tea-boxes? The other trees in the list seem too good, or rather too costly, and too heavy for tea-boxes. The only question is whether superior timbers, such as teak, may not, as we previously suggested, be made to pay as material for tea-boxes' by being sawn into very thin deals? Has anyone used teak boxes and have experiments been tried with the timbers we have mentioned by their Sinhalese names? And has the timber of *E. globulus* or any other of the Australian trees been tried? If so, information will be valued and will prove useful to the rising tea enterprize. We hope no one who has obtained light on the subject under discussion will hide it under a bushel. We may refer to a paragraph on our back page for the scientific names of trees used in Northern India by planters for tea-boxes.

Since writing the above we have received the following useful communication. *Malabada*, it will be seen, is not a good timber tree, but when well seasoned (the great point) is good enough for tea-boxes:—

April 19th, 1883.

SIR,—You ask for information regarding tea-box woods. The wood which I always use now is *Malle-bodde*, the wild nutmeg, *well seasoned*, and in this lies the secret.

This wood is very common, seasons quickly, is light and free from smell, whilst the large size of the trees makes sawing it cheap. As we all know, it is a bad timber wood, being subject to the attacks of insects, and unable to stand damp.

Sawyers will cut into planking at R3 per 100 feet: and chests and half-chests will cost, without nails, lead or hooping, 2 cents per lb. tea as an average, presuming that the timber is transported to the workshop by coolies leaving work, &c.—I am, sir, your obedient servant, T. C. OWEN.

TEA-DRYING BY STEAM.

On this subject we have received the following letter:—

Kalutara, 7th April 1883.

SIR,—I send you a rough sketch of a tea-drying machine which has been suggested to me and which recommends itself so strongly in some of its original points that I believe it quite worth while laying before the public.

The weak point, so far as I can see, in Mr. Shand's machine (and in the case of the "Sirocco" and other driers in the upper trays to some extent) is that it stews the tea: *i. e.*, that fermentation continues for some time after the leaf has been put on to dry.

This, you will see from the enclosed sketch, is entirely avoided in this machine, as each tray has its own compartment regulated by pressure to any heat it is wanted, and, by the valve arrangement on the top, over-heating is impossible, as any over-pressure would open the valve and thereby reduce the temperature to the exact point required.

Another strong point in its favour is that the heated vapour from the lower trays does not pass through the upper ones (thereby stewing the tea) but passes out behind into a vapour escape-flue: the

advantage of this must be apparent to the most uninitiated.

The cost of fuel in this machine must be comparatively very low, as there is no escape of steam except through negligence of the attendant, and, as it is self-regulating, it is impossible to burn the tea, while any heat may be maintained at a minimum expenditure of fuel.

The trays have, you will observe, a slight inclination upwards towards the vapour escape flue at the back, thus facilitating the escape of the vapour from the tray spaces, and the easy removal of the trays in working the machine.

I annex a few figures in regard to the probable pressure necessary for working the machine, but have no doubt some of your mathematical correspondents will give the correct figures should mine be "out."

15 lb pressure steam = 213° heat.
35 ,, ,, ,, = 216° ,,
70 ,, ,, ,, = 306° ,,

And as about 280° is I believe the correct heat at which to dry tea, about 57 lb or say 60 lb steam would be required to work the machine; but this could easily be determined by actual experiment. To recapitulate: its strong points are, 1st, The self-regulating valve which does away with the possibility of tea being burnt through negligence; 2nd, great economy in fuel; 3rd, uniform distribution of heat which does away with the necessity of changing the trays, and dries them exactly on the principle of firing each over a separate fire; 4th, capability of drying a large amount of leaf at once.—Yours faithfully,

TEKSAB.

The sketch which accompanied the above letter, and which quite took our fancy, represents a long array of super-imposed trays, each in its own compartment. The sketch can be seen by anyone interested, but, having submitted it to an expert, we have received the following adverse judgment:—

"Your note with Law's patent pressure steam or air dryer I had this morning. There is nothing in it, and such a machine could not be made to stand 75 lb. pressure, for a fortune, as every one knows a flat surface will never stand pressure like a cylindrical.

"Steam-drying has been tried in India many a time and has been abandoned for various reasons, and among the most important the danger of explosion from sudden expansion and contraction, two laws which, if not studied in steam drying machinery of any kind, may prove fatal to life and destructive to property." It is, of course, possible that the objections referred to may be obviated. Meantime we may say that we have noticed no stewing effects from the use of the trays in the drier. Four are placed above each other in two divisions of Jackson's drier, and, the trays being shifted (the necessity which is the one objection to this machine) the tea in fifteen minutes is dry and crisp without being burnt.

FODDER GRASSES AND HUMAN FOOD PRODUCTS FOR CEYLON.

There has been lying by us for some time the following letter received from Mr. P. D. Millie, giving suggestions from a brother of his who has been long settled in South America which deserve attention in Ceylon:—

Coquimbo, Chile.

In the Ceylon papers which you occasionally send me I see many complaints about the scarcity of fodder for cattle and horses, and the very inferior quality of meat, which of course is a natural consequence. I observe that all kinds of provisions and vegetables are likewise as a rule both inferior and scarce. At the same time, the replies to queries published, prove that very many English vegetables can be successfully cultivated upcountry, and that pumpkins, cucumbers, haricots &c., which are principally cultivated in Southern Europe, thrive in Ceylon.

The temperature in the higher districts of that island seems to present no obstacle to the cultivation of many of our Chilian vegetable products, which embrace those of both Northern and Southern Europe, and therefore I wish to make two or three suggestions which might be useful, if published in the columns of a Ceylon newspaper.

Here in Northern Chile the climate is very dry, but not exceedingly hot. English clover and grasses grew well enough, but require too much irrigation, and therefore are not cultivated. Our mainstay in the way of fodder is a kind of *lucerne*, known in California as "*Chilian Alfalfa*," and now accepted and adopted there as altogether *superior* to any other fodder plant which has ever been tried, both as regards fattening qualities and weight of produce per acre, and also as regards rapid growth. It grows well in stony or sandy soils, sending down roots to an enormous depth, but will not do well in marshy land. It grows perfectly well in Peru and Bolivia, which, in some parts, are semi-tropical countries, and I think that, if it has not been tried in Ceylon, it *ought* to be introduced. Drought simply checks its growth; but its deep roots will keep it alive for an indefinite period, without irrigation or rain. It is *par excellence* the fodder of dry countries, and I see no reason why it should not succeed in the districts of India which are subject to periodical droughts. A year's complete drought does not kill it in South America, and, with the first rain or artificial irrigation at the end of that time, it comes rushing up and produces a plentiful crop. I have never seen it mentioned in the Ceylon papers, and, if you think that it would be a benefit to the Colony, I would be happy to send you some Peravian and Chilian seed in tins, which would probably be necessary in order to preserve its vitality.

But, as you have in Ceylon much marshy land in the low grounds, I would strongly recommend the trial of another fodder plant, just discovered here to be available as such. It is neither more or less than the common *artichoke*, which we are now beginning to cultivate for that purpose.

It is one of the most easily propagated of plants, as it throws out shoots or suckers, which, when the main stem is cut down, grow up in its place. By sowing the seed in beds, the young plants can be dibbled out at the proper time without any previous preparation of the soil. If planted amongst foul weeds and "knot grass," it will speedly overtop and overpower them, thus cleansing the soil for the cultivation of vegetables or anything else. The heads can be cut off when ripe and sold as vegetables; orelse, should there be no sale, left on, and carried with the leaves to the cattle-yard, where everything is consumed.

The plants grow rapidly in marshy saline soils, and should be dibbled out at distances of four or five feet. In Ceylon very likely they would require more space than here, where the cool or cold nights perhaps check their luxuriance.

When full-grown, the main stem and superfluous root-suckers should be cut down and carried to the cattle or horses, leaving *one* healthy sucker to keep up the succession of growth. If the animals are turned into the field, they not only tread down more than they consume, but destroy all the young suckers.

I am informed that the artichoke can also be easily propagated like the potato, by cutting the roots into pieces and planting them.

Here is a new fodder plant for you, which might be a great aquisition for Ceylon. *At first* cattle or

horses may be slow to take to it, but they soon get to like the leaves, and my cousin, who is a farmer, informs me that his animals eat it most greedily, leaving nothing on the ground—heads and all disappear as if by magic in a few minutes.

As for *human* food, I recommend the general cultivation of the most suitable varieties of haricot beans. The dry beans, boiled and prepared with a little suet and Chile pepper, form the staple food of our working classes, and a hardier or more enduring set of men cannot I think be found anywhere. The first water in which they are boiled must be poured off: this is the only only hint necessary as to cooking them. My family constantly use them, and I hold them to be far better food than rice.

T. J. W. MILLIE.

[There is no fodder likely to rival the "Guinea" and "Mauritius" grass which grow so well when attended to in Ceylon.—ED.]

MR. MOENS' WORK ON CINCHONA.

When we had the pleasure and advantage of meeting Mr. Moens in Java, he allowed us look at the advance sheets of a book which was in course of being printed, and which, besides a history of the introduction of the fever trees into Asia, was intended specially to embody the result of the experience obtained by himself in the culture of all the species, and particularly the most valuable of all, Ledgeriana. We also had a sight of the series of photographs which were prepared to illustrate the book, and which, being reproduced by the Woodbury process, were perfect portraits of the plants and their parts. We understood that the Dutch Government of Java were to publish the book, and we have long looked for the announcement that it was ready, and for an early copy. We are taken by suprize, therefore, by the receipt of the following letter:—

We beg to draw your attention to a standard work on *cinchona* by Mr. J. C. B. Moens, Director of the Government Cinchona Plantations in Java, entitled 'De Kina Cultuur in Azië' 1854-1882 (The Cinchona Cultivation in Asia from 1854 until 1882), which has been published today, by the Society for the promotion of Medical Science in Netherlands India. It is a large quarto book, containing 400 pages of letterpress (in the Dutch language) and 33 full-paged photographic plates and one map, and is strongly bound in linen. The 33 chapters in which the book is divided, contain the following matter:—The discovery of the medical properties of the bark and its introduction in Europe. The cinchona tree in America. The transportation to Europe. Geographical divulgation of the trees. Climate and soil. Choice of sites and of land for making plantations. The different kinds of cinchonas found in Asia. The cultivation in Asia. The soil. The shading. The clearing and felling. The terracing. Planting. Planting distance. Seed and cuttings. Nurseries. Pruning Transplanting. Manuring. The growth. Diseases and enemies. Harvesting. Drying and packing. The trade in cinchona bark. The market. Production. Consumption. Chemical analyses and consumption of the cinchona bark, etc., etc.

The plates shew typical trees of different kinds of cinchona as grown in Java, types of bark of different kinds, leaves, flowers and seed, nurseries, grafting, etc., etc.

The price of the book is here f36 (£3) and can be obtained from, your correspondents, G. KOLFF & Co., Booksellers and Publishers.

We give gratuitous insertion and prominence to the above letter (which is really an advertisement), as a proof of the value we attach to the benefits which Mr. Moens has conferred on cinchona planters in Ceylon as well as in other parts of the world, and also as a small return for much courtesy received at the hands of the able Director of "de Kina Cultuur" in Java. We can only regret that in these hard times the price, £3, will place the work beyond the reach of so large a portion of our friends, the planters. When it is considered, however, that, besides 400 pages of letterpress and a map, there are no fewer than thirty-three plates, the price charged is really moderate. Even those who can make out but little of the Dutch text will have their money's worth in the plates. The Woodbury process either originated in Batavia or was at an early period introduced, and the name of "Woodbury" is prominent amongst the photographers of the chief city of Java. The process has been most successfully used to reproduce photographs for this work.

PLANTING ENTERPRISE IN INDIA.

In 1881 the number of tea plantations in India was 3,368 comprising an area under cultivation of nearly a quarter of a million acres, and yielding about 50,000,000 lb. of tea. In addition to the land under actual cultivation, nearly 600,000 acres have been taken up for tea cultivation. This means that, given favourable conditions to the planters, the yield of Indian tea may be quadrupled in less than ten years. The areas under cultivation, or taken up for planting, in the different Provinces, are as follows:—

	Actual cultivation.	*Taken up.*
Assam ...	158,427 acres.	548,222 acres.
Bengal ...	42,217 „	36,319 „
N. W. Provinces ...	8,445 „	3,197 „
Punjab ...	7,973 „	2,115 „
Madras (including Travancore) ...	4,447 „	4,898 „
Burmah ...	160 „	30 „

Those are the figures for tea only. The cultivation of coffee is confined almost exclusively to Southern India. The areas under cultivation, or taken up for planting, in 1881 were as follows:

	Actual cultivation.	*Taken up.*
Bengal	8 acres.	... acres.
Madras	74,236 „	59,355 „
Mysore	84,383 „	81,986 „
Coorg	47,750 „	29,724 „
Travancore and Cochin	9,920 „	12,427 „

Roughly, therefore, there are 400,000 acres under coffee and taken up for coffee cultivation, the approximate yield of coffee in 1881 having been about 40,000,000 lb., and the approximate value—at a low price—1½ millions sterling. As regards the statistics of cinchona cultivation, we find that Government had 2,328 acres under cultivation in Sikkim, with over 5,000,000 trees and plants; 83 acres at Thandoungyee, Burmah, with over 60,000 trees and plants; 41 acres in Mysore, with about 35,000 trees and plants; 847 acres on the Nilgiris, with about 3,000,000 trees and plants. The Sikkim plantations yield about 600,000 lb. of bark a year, and the Nilgiri plantations about 250,000 lb., the yield of the Madras plantations having douted since 1878. The price yielded by Sikkim bark during five years has ranged from R2-5 to R2-10 per lb.; that for Nilgiri bark from R2-8 to R3-13-5 per lb. The total expenditure and receipts on the Nilgiri plantations in four recent years were as follows:—

	Expenditure.	*Receipts.*
1877-78 ...	R69,771	R358,751
1878-79 ...	73,632	400,353
1879-80 ...	79,724	314,815
1880-81 ...	96,104	432,200

No wonder that, with such profits, private planters have rushed in to compete with Government in cinchona cultivation. The report before us gives but meagre information as to the extent of the private plantations of cinchona. A footnote informs us that "no information is available in regard to private plantations in the Nilgiris and British Burmah," a rather serious omission, so far as the Nilgiris is

and the Wynaad are concerned, for it is there where cinchona cultivation is being pushed forward so vigorously. It is estimated, however, that private plantations in Bengal yielded some 250,000 lb. of bark in 1881, the area under cultivation being 381 acres, containing about 325,000 plants. In Mysore, the private plantations are returned as only 15 acres, with a yield of 1,364 lb. of bark. In Coorg, cinchona cultivation was developed enormously during the last five years. In 1878 there were only 23,900 cinchona plants laid down, but the return for 1882 is 617,156 plants, and it is estimated that nearly 800 acres are already under cultivation, or an area nearly equal to the Government plantations on the Nilgiris. It is abundantly clear from the above figures that the cultivation of cinchona is assuming enormous proportions in Southern India, and there is every prospect of cinchona bark becoming one of the most valuable exports from India.—*Madras Mail.*

EXPORTS OF DRUGS AND CHEMICALS FROM THE PORT OF LONDON,

It is curious to note that Holland took nearly half the cinchona bark exported during February, or 17,783 lb. out of a total of 38,270 lbs. The export of aniline, valued at 1,784*l.* in February and at 4,243*l.* in January, to India, China, and Japan—at least half going to the two latter countries—gives rise to curious reflections. Hamburg shows itself the second drug market in the world by taking half the London exports of drugs, half the gum, half the essential oils, and a very considerable proportion of nearly all the other articles enumerated. Boulogne has taken the 18 cwt. of bismuth exported this year. Bruges receives more than a quarter of the rapeseed, and Belgium and Holland together absorbed two-thirds of the rape and oil seed we export. One curious item was the export of 1,950 lbs. of opium to Alexandria during January. This was anticipated in our trade report, for it is probably the "large quautity of Persian opium, which will be sent back to whence it came" (page 42, top of column 2). The opium sent to Trinidad and Guayaquill is perhaps for the use of Hindoo coolies. The enormous quantity of 700 lbs. of chloral hydrate sent to Yokohama in January is a striking circumstance.

It is, of course, absurd to believe that 5 or 10 tons represent all the alkali we export in a month, that no acids are sent abroad, that 4 oz. of quinine sent to St. Lucia in January and 500 oz. to Calcutta in February represent, even approximately, our real business in those articles. The small recorded exports of heavy chemicals represent those cleared from the port of London; but the alkali trade is done further North, and we must probably look to Newcastle and Liverpool for the true figures. Quinine is, perhaps, included under the heading "Chemicals," which must cover a large number of unspecified compounds used in small quantities. "Drugs" is another extensive heading which it would be interesting to dissect.

Doubtless our friends the exporting druggists will notice what goes abroad and where it goes, and ask themselves if they are doing their share of the business. We ask them to note, first of all, what important customers our Australian colonies are. For sponge, Genoa and New York are the largest customers for February, taking 10,728 lb., but of the remaining 1,869 lb. sent to all other parts of the world. Australia and Newzealand took 1,319 lb., besides nearly 1,600 lb. in January. Of corks 67,252 lb. were exported in February to all parts of the world, 37,212 lb. going to the Antipodes. A sixth of the essential oils, a fourth of the almonds, more than a third of the chemicals, three-fourths of the ether and a fifth of the chloroform, nine-tenths of the licorice, a fourth of the castor oil, a sixth of the perfumed spirit, three-fifths of the transparent soap, half the olive oil, nearly all the train and cod oil went to that part of the world. The proportion of licorice consumed there is curious, and seems more like the state of things in America than in the mother country.—*Chemist and Druggist.*

INDIA: CROP AND WEATHER REPORT.

FOR THE WEEK ENDING THE 10TH APRIL 1883.

(From the *Pioneer*, April 17th.)

GENERAL REMARKS.—Slight rain has fallen in a few districts in the Madras Presidency, in the Punjab, in British Burma, and in parts of Bengal proper. There has also been some rain in Mysore and Mercara and in Cachar. Elsewhere there has been no rain to report during the week.

The harvest of summer ragi, cholum, and paddy continues in nearly all the districts of the Madras Presidency, and prospects are good, except in Madura, where the standing crops are reported to have failed in parts. In the Bombay Presidency the rabi harvest is over; sugarcane is being planted in parts; scarcity of drinking-water still prevails in some places in Dharwar. Locusts have reappeared in the Dekkan districts, and measures for their destruction have been commenced in Satara. In the Bengal Presidency the rabi harvest is for the most part over, with generally a fair outturn: rain is much wanted throughout Bengal proper for general ploughing, and for sowing of autumn crops and also for standing crops in Orissa. The rabi harvest is in active progress throughout the North-Western Provinces and Oudh, and has been nearly completed in some places. Prospects are good; but rain is wanted in Kumaun for late rabi and for kharif sowings. Harvest operations have commenced in two districts of the Punjab, and prospects are generally good. In the Central Provinces harvest prospects are good, and in one district the rabi outturn is reported to be above the average. In Assam ploughing and sowing is reported to be in progress. In Mysore and Coorg paddy and sugarcane has been more or less harvested in all districts, and in the Nizam's territories reaping is still in progress. In the Central India States and in Rajputana the harvest is in progress and prospects are good.

MADRAS.—General prospects good.

THE EMPLOYMENT OF COCOA MEAL in the rations of French cavalry horses has produced such satisfactory results that the practice will be continued permanently.—*M. Mail.*

SYLHET TEA DISTRICT.—An ex-Colombo resident, who has gone to assist on a tea estate in this division of Northern India, writing on the 8th April says:—"The heat here is intense."

PUNERIA BERRY.—The plant "Puneria" known to Botanists as Withania Coagulans, and common in the Trans-Indus tracts and along the salt range up to an elevation of 4,500 feet, yields a berry which the Afghans and Beluchis use for curdling milk to make cheese, and it occurred to Sir James Fergusson, the Governor of Bombay, that it might form a cheap substitute for rennet. Accordingly, a consignment of the berries was sent to the Kilkerran estate, the property of His Excellency, and distributed to some of his tenants who instituted a series of experiments which were most successful, the small number of failures being attributed to the use of hot instead of cold water in steeping the berries. The cultivation of the plant is being tried at the Government Botanical Gardens at Saharanpur, and it is believed that it would grow almost in any part of the north-west of India. Withania Coagulans does not grow in Southern India, but Withania Somnifera does, and as it would be interesting to compare the results obtained by the use of the two allied species, the local Government have directed the attention of Mr. Wilson, Director of Agriculture, Dr. Bidie, and Professor Lawson to the subject.—*Madras Standard.*

ROYAL BOTANIC GARDENS.

REPORT OF THE DIRECTOR FOR THE YEAR 1882.

I.—THE GARDENS.

1.—Péradeniya Garden.

A great deal of heavy work has been got through during the year, nearly everything planned at the close of the previous one having been carried out.

Roads and Paths.—It was mentioned in my last report that extensive repairs had become necessary to nearly all the main driving thoroughfares in the garden, and accordingly much of our labour during 1882 has been expended on this work. Those in the garden itself are now in good order, and the remainder in the old arboretum, which need much remaking, will be put into proper condition in the coming season. The roads by the fernery, round the small circle, near the stores and the Director's house, have been completely remade, as well as those at the entrance and from thence to the lake. Culverts have been put in where necessary, and opportunity taken to make some alterations in their course and to remove old trees and straggling vegetation in too close proximity. The long drive in the new garden was completed early in the year.

Two new footpaths have been made—one from the fernery to the small circle, the other along the course of a long disused drive by the old nursery and bordered by a grove of very fine old specimens of Java almond trees (*Canarium commune*). These open up parts of the garden not previously accessible to visitors.

Buildings.—An estimate for necessary repairs to the Assistant Director's bungalow—now for a year unoccupied—has at length been sanctioned, but these have not yet been commenced.

The little monument erected in 1855 as a cenotaph in memory of Mr. Gardner—the well-known botanist and traveller who preceded Dr. Thwaites as Superintendent of the garden—had fallen into very bad repair and is now undergoing renovation. This I have been enabled to undertake with the aid of a small balance of the sum originally subscribed, which had remained in Dr. Thwaites' hands. It is hoped that sufficient may remain to obtain and affix a small memorial tablet as originally intended by the subscribers.

The glass-roofed plant-shed proposed in my last report has been built during the year. It is 40 feet long by 15 feet wide, and the roof is supported by ten cylindrical red brick pillars; the floor is also of brick and is well drained. The appearance is very light and ornamental, and will be more so when the staging and blinds are put up. This has been a rather expensive building, but the cost has been entirely met out of the ordinary votes for the garden. It will be used for the safe keeping and exhibition of the choicer pot plants, orchids, &c., which are easily lost when planted out amidst the exuberant vegetation of the garden.

The old carpenter's shed having fallen in during the extremely wet weather of July, a new and substantial brick-pillared and tiled building has been erected for the use of the carpenter and his assistant. In this case also there has been no application to Government for funds.

Lawns.—A special vote having been included in this year's estimates for the purchase of a large mowing machine, I took advantage of a visit to England to make the necessary inquiries, and ultimately selected Messrs. Samuelson's "P. Balance Draught" grass-mower, with certain modifications to fit it for traction by bullocks. This machine has arrived, and I anticipate a very great saving of labour by its use.

It is necessary, however, to first bring our extensive tracts of grass into a fit condition, and the whole will be gone over carefully with this object. The stumps of old trees and bushes have to be dug out as well as numerous ant-hills, much levelling is necessary, and quantities of stones and rubbish have to be removed. When this is finished, and the grass regularly cut and attended to, very fine lawns will be produced.

Propagation and Planting.—The planting up of the new arboretum formed a principal part of the work during the wet season. The unusually prolonged rains during the past year have been very favourable for this, and very few plants have been lost. The trees of the natural families—*Sapotaceæ, Ebenaceæ, Bignoniaceæ, Verbenaceæ, &c.*—have been planted in their position in the new garden where the *Bixaceæ, Pittosporaceæ, Rutaceæ*, and *Capparideæ* have been also allocated.

As I expected, however, this addition to the garden has not been found sufficiently extensive to accommodate the whole of the classified collection of trees. I have therefore concluded the arrangement in a convenient part of the old arboretum. There have been commenced the natural orders—*Magnoliaceæ*, *Anonaceæ*, *Guttiferæ*, *Dipterocarpaceæ*, *Malvaceæ*, *Stercaliaceæ*, *Tiliaceæ*, *Meliaceæ*, and *Sapindaceæ*. To make way for this, a number of cocoanuts planted some 25 years ago (and a constant temptation to pilfering) were cut down and dug out.

The woody monocotyledons are all to be accommodated in the new garden, and all that are available have been put in their places. The *Palms* are of course the most important. The planting of the great crescent with these commenced in June, and about 80 species have been successfully established; many more are coming on in the nurseries and pots, and will be put out next season. The crescent is 285 feet across and 114 feet in depth at its centre, and the attempt is being made to arrange the palms in such a way that while their affinities to one another are exhibited, the harmonious and picturesque effect of the whole group shall be kept in view. The fan-leaved kinds occupy the two horns (the smallest species at the points) whilst the central parts contain the far more numerous groups with feather-leaves. It has been an object to keep the species of different genera together, and attention has also been paid to the relative heights of the adult trees, the smaller kinds occupying the front and those of gradually increasing size being placed in series behind one another. Though such an attempt can be expected to prove only moderately successful—being interfered with by such causes as relative rate of growth, suitability of soil, site and climate, and want of information as to size and habit—it may be expected that this palmery will in time present a very magnificent spectacle.

The other allied families—the screw pines (*Pandanaceæ*), bamboos and other large grasses, aloes, *Musaccæ*, &c.—have been planted in order by the carriage drive round the palms. The collections of *Cycadeæ* also finds a place here: these were planted in November.

A good commencement has also been made in planting up the *Herbaceous Ground*. The space was first partitioned out among the natural orders, and the stocking commenced in May with collections brought in by the collectors from the jungle. It is being continually added to, and is already proving of great assistance. I have also begun the planting of the proposed series of woody creepers and twiners on the steep bank of the high road. Along the top of this the wet weather enabled the hedge of dwarf bamboo, which had twice been replanted, to become at last, I hope, well established.

There is thus now provided a general systematic garden for both arboreous and herbaceous plants, and new species as they arrive find their places in it. This has been effected with no disturbance, by any formal arrangements, of the picturesque natural character for which this garden is so well known.

The fernery, always one of the most attractive spots in the garden, had lost much of its beauty and utility, and has been almost entirely renovated. The common native ferns and many spontaneous weeds had gradually prevailed over the others, and the soil had been washed away and choked the water-courses. These latter and the paths have been repaired, the old soil of the beds dug out and replaced and the surface covered with small broken pieces of cabook, and the whole replanted with a larger variety of species.

A selection of succulents and sun-loving species has been put out on the rock-work near the lake. The circular flower bed near the store has been raised and turned into a rockery, a water-course being conducted round it in a brick channel: other unsatisfactory borders around have been laid down as grass. The place is too much shaded by trees for flower beds. This change, with the clearing away of much undergrowth, has greatly improved this portion of the garden.

Labelling.—Of the zinc-painted labels only about 300 have been fixed this year, and of these many were to supply the place of former ones already destroyed by the climate. In the shade these labels are fairly satisfactory, some now 18 months in position being as good as when put up, but in positions exposed to the sun some other sort will be necessary. The paint in such situation quickly cracks and in a few months the writing is illegible, or it detaches itself altogether from the zinc and peels off. Experiments will be made with printed labels, protected from insects by poison. The whole question of properly labelling the collections is a most difficult one to solve in this climate and with our resources.

Visitors.—The number of visitors to the garden has shown a very marked increase, since the transfer of the Mail Steamer port to Colombo has enabled travellers to avail themselves of the Kandy railway. Of these, Australians form a large proportion.

Meteorological Observations.—I beg leave to repeat the request already made, that sets of simple instruments (adjusted in accordance with those at the Surveyor-General's Office) may be supplied to the three gardens. A weather record at Hakgala is especially desirable, as, apart from its botanical utility, it would be of quite exceptional meteorological value. I trust that this want may be supplied as soon as possible.

2.—Hakgala Garden.

It is with much satisfaction that I am able to record the revival of this garden from past stagnation, and the promising commencement of the course planned out in my last report. In the superintendent, Mr. Nock, I have an officer capable of entering into my plans with intelligence and zeal, and on whose practical experience I can rely to carry them out with success.*

The repairs to the water-course have occupied at intervals a good part of the year and have been satisfactorily carried out by the Public Works Department. Want of water was fortunately, owing to the wet weather, not much felt. It now runs freely, and it is hoped that the course will give no further trouble. The storeroom and outhouses have also been reshingled and whitewashed by the Public Works Department.

The improvement most needed at Hakgala is an extension of the present carriage drive. The attention of Government has been called to this during the past year, and though it has not been found possible to afford me any extra grant for labour at present, I purpose to make a commencement on this most desirable piece of work at once. At present the drive suddenly terminates exactly in front of the superintendent's bungalow, and, as it is at this spot only that carriages can turn all must proceed hither, and hence return by the way they have come. I intend to construct a continuation, leaving the present road before that reaches the bungalow, passing through the lower part of the garden and shrubberies, and curving round back to the entrance-gate. The whole of this continuous drive is planned out; it will take in some parts of the garden now scarcely seen, and include the fine view across the Uva country. The length of this addition to the drive is 495 yards, but I purpose at present to complete a portion only, 135 yards in length, to a level spot where a carriage-house and sheds can be built for the convenience of visitors. Hence a foot-path will be made in the line of the proposed extension.

My strongly-urged request to Government for a propagating house having been very liberally granted, I prepared, in conjunction with Mr. Nock, a plan of what was required, and during my visit to England, made arrangements for its construction by Messrs. Boyd, of Paisley. It is expected to arrive out early in the present year, and its erection will be at once proceeded with. This will very greatly add to the efficiency of the garden.

The superintendent has, at my request, submitted to me a detailed report on the work of the year in the garden, from which large extracts are given below. A catalogue of the plants growing in the garden has also been compiled; the exotic (not Ceylonese) species and varieties amount to over 600.

"*Buildings*.—In the superintendent's bungalow the plaster in several places has become cracked, and has fallen off in others; and the whole building requires white washing and repainting: otherwise it is in good order, the locks and bolts to the doors and windows having been repaired during the year.

"Quarters consisting of four rooms have been erected for the foreman out of the ordinary vote for upkeep, the greater part of the work being done by the workmen employed in the garden.

"The small dilapidated propagating house has given way several times during the bad weather, and on one occasion a considerable number of grafted Ledgeriana plants were destroyed. The plants in it have to be continually moved about to try and avoid the drip and draughts, and I regret to say that many valuable seedlings have been lost during the year for want of proper propagating accommodation.

"The cooly lines, the carpenter's shed, and the potting shed are still in a very leaky state, and will require to be thoroughly repaired during this year. In the potting shed a substantial bench has been fitted up, and the work can now be carried on in a satisfactory manner.

"One of the cart sheds near the bungalow, that was used by persons visiting the garden as a shelter for horses and carriages, was blown down during the S.W. monsoon, and the one used for the garden carts, &c., was considerably damaged. The site of these sheds being very

* During my absence from Ceylon, Mr. Nock acted for me officially, and thrice visited Pérádeniya.

inconvenient, it is not thought advisable to build another in the same spot as the one blown down, or to spend much labour in repairing the other, as a much more convenient site can be found for them as soon as the proposed new drive is made.

"*Carriage Drive and Paths.*—The carriage drive at the entrance gate has been remade for a distance of 90 feet, and turf laid down on each side. Inside the gate for a distance of 66 feet an edging of turf has been made on each side, and a flower border on the lower side. The drain on the upper side for a distance of 300 feet has been repaired, stone edgings laid down on each side of the drive for the same distance, and a margin of *Sedum*, 12 inches wide, planted. This was planted here in consequence of the trees above giving too much shade for turf. The rest of the drive is still in bad condition, and it is intended to remake this as soon as possible and place an edging of *Sedum* or turf on each side. A quantity of materials has already been got together for this purpose.

"All the old paths were in very bad condition, and these for a total length of 1,049 yards have been broken up, large stones and roots removed, the surface levelled down, and a layer of rough sand stamped in on those most used, and a drain made on one or both sides, as was required, for the same length. Two hundred and eighty yards of new paths have been made in various parts of the garden. A great deal has still to be done to the paths in the way of edging, forming drains, and in making the surface firm and even. Until they become uniformly hard they will require constant attention in filling up holes, &c., as the drip from the trees with a few hours' rain works out the surface gravel in the loose places and carries it away.

"*Fernery.*—The old fernery, which had become very much overgrown with jungle, has been opened out, and the soil in the beds, which was nothing more than a mass of matted roots from the surrounding trees, was taken out to a depth of 12 to 14 inches and replaced with leaf mould and surface soil from the jungle. The whole has been replanted with native ferns from the surrounding districts, mixed with Begonias and a few other suitable plants. The approach to the fernery, which was in the worst possible condition, has been newly laid out. A winding path 4 feet wide and 108 feet long has been made, with a shallow paved drain 1 foot wide on each side; and a low rock bank formed on each side, on which have been planted small ferns and Begonias. The small paths winding through the fernery have all been made even and rough sand placed on the surface. The appearance of the fernery has thus greatly improved, and is now much appreciated by visitors. This situation is so favourable for the growth of ferns, that I feel sure there could be found at least 500 or 600 species that would thrive here. I have now, as a commencement, a considerable number raised from spores of foreign species, but they are still small plants, and it will be some months before they will be fit to plant out. It is intended to grow with the ferns as many of the native and foreign orchids as can be secured suitable to the climate, and several of the native species have been brought in for this purpose.

"*Ornamental Pond.*—The trees and shrubs bordering this pond have been thinned and pruned, and several suitable trees and plants planted where required. The old arbour here, placed in a very inconvenient spot, has been taken down, the hollow filled up for a distance of 36 feet from the pond, and a new arbour erected. This commands a very fine view of the Hakgala rock, which, though not more than a mile off, is about 1,400 feet higher. A small winding path has been made from the arbour through the shrubbery into the main drive, with flower borders on each side edged with turf. The old path on the lower side was remade and turf edgings laid down. Flower borders were also made round the arbour, and one on the lower side of the old path. An ugly bend in one part of the pond was taken off and the soil used for filling up the hollow abovementioned. In the border on the lower side of the pond examples of each of the varieties of roses growing in the garden have been planted.

"*Herbaceous Garden.*—A commencement has been made to get the herbaceous plants together, and nine beds have been made in a part of No. 3 nursery where 233 species have been set out and labelled, arranged according to their relations. Most of them have been raised from seed received (from various sources) during the year, and the majority of the plants are as yet small; but as there are many species of economic value, the garden will no doubt prove interesting and useful to visitors. Besides, much time will be saved in collecting seed as they are growing side by side and all named.

"*Borders and Shrubbery.*—The soil in the old borders has been renewed, new borders have been made and planted—generally with mixed plants. This plan of planting has not answered so well as was desired, as the plants soon run into one another and assume a wild, uncultivated look.

There is also the difficulty, when taking cuttings, unless they are in flower, of knowing one from another. In future I propose to plant in clumps or chain fashion, and keep each kind as distinct as possible.

"The work of thinning and pruning has been carried on as time allowed, and several hundreds of loads of thinnings and prunings have been taken out. There is still a very great deal to be done in this way, and until a large number of the remaining unshapely trees have been taken out so as to admit light and air, it will be impossible to make this part look as bright and cheerful as is desired. Holes have been made under and about the trees wherever there was a chance of a plant growing, and several thousand herbaceous plants have been set out in them. Each plant received manure and sand, where required; but although a large proportion have done well, a considerable number have been almost killed by the hungry roots of the trees running in and taking up all the nourishment that was intended for the plants. In many cases examined I found that the roots from the trees had taken full possession of the soil in six weeks. The trees that have been pruned and the light let in round about them have very much improved, and a good many promising specimens are now to be seen where a perfect jungle existed twelve months ago. Nine thousand seven hundred and sixty-five garden plants have been planted out in the borders and shrubbery during the year.

"*Flower Garden.*—The large ungainly trees along the edge of the flower garden have been entirely rooted out and a low wall built in their place. In the joints of this wall were planted the naturalized *Calceolaria* and *Browallia*, with a few other things. The old flower garden, which was laid out in shingle-edged beds, was all dug up, levelled and turfed over, and in this has been cut a design of 26 beds with a narrow border running all round. The usual showy garden plants have been planted, and on the whole have done well, though, owing to the continuous wet weather, there has not been any great show of bloom.

"*Eucalyptus Plantation.*—Forty-three different species of Eucalyptus have been planted out in the semi-abandoned cinchona clearing. They are planted in clumps of five, each clump being 25 feet apart. The soil is very poor here, but the plants have made a good start, and it is hoped will soon make fine specimens.

"*Cinchona clearings.*—The remaining trees of C. *Calisaya*. *Ledgeriana* and *officinalis* in these clearings have continued to die out, and all those that showed signs of going off, as well as the old C. *succirubra* trees planted in the jungle which were in the same condition, were uprooted and barked: they yielded 1,472 lbs. of dry bark. (*For particulars see p.* 10 D.)

"In accordance with instructions, a small plantation has been prepared with the object of exhibiting type-specimens of cinchonas, and in it have been planted examples of fifteen kinds. The site for each plant was specially prepared, large holes being made and nine inches to a foot of drainage placed in the bottom of each. The holes were filled in with surface soil from the jungle, enriched with well-decomposed cattle manure. The plants are all alive, but I regret to say have made hardly any growth, and I am afraid that with the best of treatment we shall never be able to make a satisfactory cinchona plantation here even on such a small scale.

"*Visitors.*—The number of visitors during the year was 370.

"*Weather.*—I regret exceedingly, not being able to give full particulars of the weather, not having yet been supplied with instruments for this purpose; but the following remarks may probably be interesting. Rain fell on 235 days, counting from 14th of January, the date of my taking over the charge of the garden, as follows:—

January (14—31)	rain on	10	days	September	...	rain on	27 days
February	... do.	16	do.	October	...	do.	27 do.
March	... do.	6	do.	November	...	do.	20 do.
April	... do.	12	do.	December	...	do.	22 do.
May	... do.	15	do.				
June	... do.	18	do.			Total ...	235
July	... do.	31	do.				
August	... do.	31	do.				

Rain fell on every day from the 25th June to 23rd September, with one exception—the 13th September.

High winds prevailed from the 18th May to the middle of September, at times almost blowing a hurricane.

The weather on the whole was very unfavourable for garden work, the greater part being too wet for planting; and the damp sunless weather proved fatal to hundreds of succulent plants. It appears that the year 1882 has been exceptional, both as regards rain and wind, but no record has hitherto been kept here so far as I am aware. Such a record would be very interesting, as the weather appears to be quite different a few miles away on either side. We often have heavy rain here when a mile away there has not been a drop."

3.—Henaratgoda Garden.

This continues to fulfil admirably the purposes for which it was instituted. Indeed, as the useful plants of tropical low-lying regions are being successively introduced, it is becoming more and more valuable. Such purely equatorial species, as the gutta-perchas and the majority of the india-rubbers, the Brazil nut, the cow tree, and many others, which make very slow progress at Péradeniya (some have even died off here), are very much more at home in the lower garden, where they grow with vigour and rapidity. The higher night temperature seems to be the principal cause of this great difference.

During the year the roads in the garden have been remade and new nurseries laid out. A number of crowded trees have been rooted out and new nurseries for Burmah and African rubbers made. Another rose bed has been formed.

The garden having become a rather favourite spot for excursions from Colombo, a small but substantial covered erection has been put up near the conductor's house for the accommodation of visitors. I am glad to see from the visitors' book that so many persons have been to this interesting and instructive garden (including the botanical class of the academy) during the year.

The behaviour of the conductor remains uniformly excellent, and his management of the garden such as to merit my continued warm approbation.

The results of an experimental tapping of the *Hevea* and *Castilloa* rubbers will be found at page 12.

With the view of improving the approach to the gardens from the railway station, I have suggested to the Government Agent the desirability of planting an avenue of shade trees along the straight hot glaring road. As my proposal has been met very cordially, this work will be carried out under the conductor's supervision during the next rainy weather.

Anurádhapura.—The small experimental garden at Toluwila, close to the ancient capital of Ceylon (referred to in last year's report) has been transferred to my Department, and the charges for its upkeep appear on the votes for 1883. I have had much trouble in persuading any suitable man from the Péradeniya staff to remain in this garden owing to the prevalence of fever, but have at length obtained a capable and intelligent native who has had many years training and experience in Péradeniya, who took charge in October. Unfortunately, the results of his work were in December entirely destroyed by a flood. The unusually heavy rains of that month submerged the garden to a depth of several feet, and all the young plants and seedlings recently put out perished. This misfortune has shown that it will not be wise to retain the garden in its present situation. This is just beneath the great bund of the Tissáwewa tank, and in heavy rains the water unable to get away regurgitates from the bund and floods the land. It is my intention to select a new site in a better position nearer the town, and the Government Agent, who agrees with me as to the necessity of the step, has already suggested a suitable locality.

II.—Interchange of Plants and Seeds.

The exchange between the gardens and similar public establishments in other countries has been vigorously maintained, and as is seen by the appended lists, many valuable plants have been added to the collections. At the same time, experience shows that it is not possible to obtain in this way quite all the sorts of plants that the public hope to see in the gardens. I should therefore be glad if liberty were accorded me to *purchase* (out of the vote for contingencies) certain seeds and plants which cannot otherwise be obtained. This power would be rarely exercised, but florists' flowers, the better sorts of fruit trees, grass seeds, &c., can be acquired only (apart from gifts) through the trade.

During the year, wardian cases have been received from the Botanic Gardens at Kew (4), Calcutta, Buitenzorg, Hongkong and Brisbane; from the Agri-Horticultural Society of Madras; from the Deputy Commissioner for the Andamans; and from Messrs. Veitch, of Chelsea.

On our part, cases have been sent out to the Gardens at Kew (2), Calcutta (2), Ootacamund, Singapore, Buitenzorg and Hongkong; to the Agri-Horticultural Society of Madras; to Rajah Brooke, of Sarawak; and to Messrs. Veitch, of Chelsea, and Mr. Roberts, of Melbourne.

Packets of seeds have to be acknowledged from the Botanic establishments at Kew, Dublin, St. Petersburg, Calcutta, Saharunpore, Ootacamund, Singapore, Hongkong, Buitenzorg, Jamaica, and Demerara.

Seeds, &c., have been forwarded to the Government gardens at Kew, Dublin, Calcutta, Saharunpore, Ootacamund, Singapore, Buitenzorg, Hongkong, Brisbane, Jamaica, and Demerara; to the Royal Botanic Society of London, the Horticultural School of Belgium, and the Agri-Horticultural Society of Madras; to the Colonial Secretary of Western Australia; to the Secretary to the Bombay Government, and to the Conservators of Forests, Madras and Assam; also to Messrs. Bull and Messrs. Veitch, of Chelsea, and to Mr. Roberts, of Melbourne.

Plants and seeds have been delivered gratis to the Government Agents at Kandy, Ratnapura, Kurunégala, Anurádhapura, Vavúniyan-Vilánkulam, Jaffna and Mullaittívu; to the Police Barracks, Kandy, and to the Municipality of Colombo.

For gifts of seeds or plants to the gardens during the year, I have to thank the following:—Sir H. Lefroy, K.C.M.G., &c.; H. Low, C.M.G. (Perak); Hon. M. Lister (Sunjei Ujong); T. Christy (London); L. B. von Donop (N. Borneo); Mr. H. Starling (Bombay); Sir F. von Mueller, K.C.M.G. (Melbourne); Mr. Cresswell (Sydney); and M. J. de Cock (Ghent); and in the Colony, His Excellency the Governor, Mrs. Baker, Mrs. Ellis, Mrs. Harvey, Messrs. Anwardt, Capt. Bayley, A. B. Braine, L. Brown, W. J. Cotton, R. E. Falls, W. Ferguson, F.L.S., A. H. Macartney, T. H. Moorhouse, H. Nevill, C.C.S., J. C. Roberts, W. G. Sandison, H. S. Saunders, F. S. Stephens, C. E. Welldon, J. Westland, W. H. Wright, and the Ceylon Company, Limited.

III.—Additions to the Collections.

The following are the more interesting exotic plants added during the year. I was able during my leave in England to visit the Royal Gardens at Kew, and with the kind assistance of Sir Joseph Hooker, to make a selection from their duplicates of both tropical and temperate species suitable for the gardens here. Many desiderata have been thus supplied.

1.—Péradeniya and Henaratgoda Gardens.

DICOTYLEDONS.

Wormia Burbidgei, Hk. f. N. Borneo. Figured in Bot. Mag. 6531. (Kew.)
Canella alba, Murr. The "wild cinnamon" of the West Indies: the bark long used in medicine. (Kew.)
Pittosporum melanospermum, F. M. Queensland. (von Mueller.)
Garcinia (*Xanthochymus*) *dulcis*, (Roxb.) Moluccas. (Singapore.)
Malvaviscus multiflorus, Spach (*Pavonia*, Juss.) Brazil. (Kew.)
Sterculia acerifolia, A. Cunn. The "Flame-tree" of N. S. Wales; very ornamental. (Roberts, Melbourne.)
——— *diversifolia*, G. Don (*Brachychiton populneum*). One of the "Bottle Trees." N. S. Wales. (Id.)
——— *ramiflora*, Benth. N. Australia. (Id.)
——— *trifida*, (Id.)
——— sp. (Saharunpore.)
——— sp. "Macoque." (Kew.)
Melochia velutina, Bedd. (*Visenia*, Voight.) India. (Madras.)
Elæocarpus (*Monocera*) *lanceolata*, Hassk. Java. (Buitenzorg.)
Guaiacum officinale, L. The wood "Lignum Vitæ" is remarkably hard and tough, and yields a peculiar stimulant resin used in medicine. W. Indies. (Jamaica.)
Murraya, sp. (Roberts, Melbourne.)
Ailantus moluccana, DC. Moluccas. (Buitenzorg.)
Flindersia australis, R. Br. Queensland. (Brisbane.)
Carapa guianensis, Aubl. Trop. America and W. Trop. Africa. (Brit. Guiana, 1881.)
Ilex paraguayensis, St. Hil. The "Yerba" of Paraguay. Leaves afford "Maté" or Paraguay Tea, the favourite drink of the Spanish Americans. (Madras and Kew.)
Enonymus sp. nov. Affords the "Paich'ha" (= White Tea) wood in which the well-known Ningpo carvings are wrought. (See Kew Report, 1878, p. 41.) (Hongkong.)
Catha edulis, Forsk. "Arabian Tea." Native of Abyssinia, much cultivated, like coffee, in Arabia: the leaves and twigs, called "Kât," are made into a stimulant drink and also chewed. (Kew.)
Cissus porphyrophyllus, Hort. Very ornamental foliage. (Kew.)
Paullinia caracasana, Jacq. Trop. S. America. (Kew.)
Crotalaria, sp. nov. Australia. (von Mueller.)
Sophora, sp. Trinidad. (Buitenzorg.)

Glycine (Soja) hispida, Moench. "Soy Bean," Japan and China: a good food, and foundation of a well-known Japanese sauce. (T. Christy.)
Millettia megasperma, F. M. Queensland. Figured in Bot. Mag. 6541. (Roberts, Melbourne.)
Pterocarpus echinatus, Pers. Philippines. (Buitenzorg.)
Hymenæa Courbaril, L. W. Indies. (*Ib.*)
Lysidice rhodostegia, Hance. S. China. (Hongkong.)
Afzelia (Intsia) amboinensis, Thouars. Java, &c. (*Ib.*)
Blakea trinervia, L. Jamaica. (Kew.)
Begonia ulmifolia, Willd. Trop. S. America. (*Ib.*)
Gardenia megasperma, F. M. N. Australia. (von Mueller.)
——— *citriodora*, Hortor. (Veitch.)
Ixora Colei, Hortor. (*Id.*)
Notonia corymbosa, DC. S. India. (Madras.)
Ardisia, sp. Penang. (Calcutta.)
Bassia latifolia, Roxb. The "Mahwa" of Central India. The sweet fleshy corollas afford a nourishing food and a spirit. (Madras.)
Dichopsis, sp. Perak. Affords "Gatah Taban Putih," a good sort of Gutta Percha. (H. Low.)
Noronhia emarginata, Thouars. Madagascar. (Madras.)
Landolphia (Vahea) madagascariensis, (DC.) Madagascar. Affords an India Rubber. (Kew.)
Strophanthus longecaudatus, Wight. Malaya. (*Ib.*)
Ochrosia (Lactaria) acuminata. (Buitenzorg.)
Tabernæmontana pubescens, R. Br. Queensland. (Roberts, Melbourne.)
Buddleia madagascariensis, Vahl. Madagascar. (Kew.)
Drymonia punctata. Trop. America. (*Ib.*)
Dolichandrone falcata, Scem. S. India. (Buitenzorg.)
——— *Cauda-felinæ*, Benth. China. (Hongkong.)
Acanthus montanus, Hort. Madr. (Madras.)
Eranthemum, sp. (Kew.)
Ruellia flagelliformis, Roxb. Moluccas. (Calcutta.)
Beloperone elongata. Trop. America. (Kew.)
Clerodendron fragrans, Willd. (fl. pleno.) Japan. (Veitch.)
Salvia atropurpurea. (Calcutta.)
——— *glutinosa*, L. S. Europe. (Saharunpore.)
Melanocarpum Sprucei, Hk. f. (Pleuropetalum costaricense, *H. Wendl.*) Ecuador, Mexico. (Kew.)
Rivina flava, Hortor. Trop. America. (*Ib.*)
Coccoloba dubia. Trop. America. (*Ib.*)
Nepenthes superba
——— *intermedia* } Hybrid Pitcher-plants. (*Ib.*)
——— *Dominiana*
Peperomia resedæflora, Andrè. New Grenada. Figured in Bot. Mag. 6619. (Kew.)
——— *maculosa*, A. Dietr. Peru. (S. Petersburg.)
Cinnamomum Cassia, Bl. The source of the "Cassia lignea" of commerce. S. China. (Hongkong.)
Phyllanthus atropurpureus, Hortor. (Kew.)
Acalypha illustrata, Hortor. (Calcutta.)
Broussonetia papyrifera, Vent. The "Paper Mulberry." China, Japan, and Burmah. The very strong paper of Japan is made from the inner bark. (Calcutta.)
Gnetum Gnemon, L. Malay Archipelago. Leaves, flowers and fruit eaten by the natives. (Kew.)
Cycas media, R. Br. Queensland. (Hongkong and Melbourne.)
Macrozamia sp. ("Cycas.") (Roberts, Melbourne.)

MONOCOTYLEDONS.

Cienkowskia Kirkii. (Kew.)
Musa coccinea, Andr. China, Java, &c. (*Ib.*)
——— *superba*, Roxb. India. (Singapore.)
——— *Cavendishii*, Paxt. China. (Veitch.)
Phajus grandifolius, Lour. China. (Kew.)
Epidendrum bicornutum, Hook. Trinidad. (Kew.)
——— *virens*, Lindl. Trop. America. (*Ib.*)
——— *Lindeni*,
——— *purum*, } (Kew.)
——— *aromaticum*,
Schizocapsa plantaginea, Hance. S. China. A new genus of *Taccaceæ*. (Hongkong.)

Morœa Robinsoniana, F. M. "Wedding Flower." Lord Howe's Island. (Cresswell, Sydney.)
Hœmanthus albiflos, Jacq. Cape. (Kew.)
Vallota purpurea, Herb. Cape. (*Ib.*)
Hymenocallis caribbœa, Herb. W. Indies. (Veitch.)
Crinum Careyanum, Herb. Mauritius. (Kew.)
——— *Moorei*, Hk. f. Natal. (*Ib.*)
Eucharis candida, Planch. New Grenada. (*Ib.*)

Palms.

Kentia Wendlandiana, F. M. (*Hydriastele*, Wendl.) Queensland. (Brisbane.)
——— *Macarthuri*. (Singapore.)
Euterpe, sp. Dominica. (Kew.)
——— *montana*, Grah. Venezuela and New Grenada. (*Ib.*)
Ptychosperma singaporensis, Becc. Singapore. (Calcutta.)
Oreodoxa sp. Brit. Guiana. (Kew.)
Manicaria saccifera, Gaertn. "Bussú" Palm. Brazil. (Kew.)
Ceroxylon andicola, H. & Bonpl. (*Iriartea*, Spreng.) Wax Palm. Andes. (*Ib.*)
Wallichia caryotoides, Roxb. Malaya. (Calcutta.)
Phœnix acaulis, Roxb. India and Burmah. (Jamaica.)
——— *tenuis*, Hortor. (Roberts, Melbourne.)
Caryota sobolifera, Wall. India and Malaya. (Singapore.)
Copernicia cerifera, Mart. "Carnauba" Palm. S. Brazil. (W. Ferguson.)
Thrinax excelsa, Lodd. Jamaica. (Jamaica.)
Sabal, sp. (Roberts, Melbourne.)
Bactris, sp. (Kew.)
Diplothemium maritimum, Mart. Brazil. (Roberts, Melbourne)

Epipremnum mirabile, Schott. Malay Islands, Fiji, and Trop. Australia. The "Tonga"; said to be a valuable remedy for neuralgia. (Kew.)
Godwinia gigas, Seem. (*Dracontium*, Engl.) Nicaragua. One of the largest known aroids. (Madras.)
Veltheimia viridiflora, Jacq. Cape. (Kew.)
Drimiopsis Kirkii, Baker. Zanzibar. Figured in Bot. Mag. 6276. (Kew.)
Schœnocaulon officinale, A. Gray. Central America. Affords "Cevadilla" seeds. (Kew.)
Yucca aloefolia, L. W. Indies and Mexico. (St. Petersburg and Jamaica.)
——— *baccata*, Torr. California and Mexico. (Kew.)
Cordyline stricta, Endl. Queensland. (Roberts, Melbourne.)
Dasylirion serratifolium, Karw. and Zucc. Mexico. (Roberts, Melbourne.)
Asparagus plumosus, Baker. Cape and Natal. (Kew.)
Dichorisandra undata, Linden. Brazil. (Kew.)
Mapania sp. (*Hypolistrum trinervium*, Hort. Calcutta.)
Andropogon Schœnanthus, L. "Ginger grass." N. and Central India. Affords Rúsa ("Rose") oil, "Oil of Geranium," and "Oil of Namur" of commerce.

2.—Hakgala Garden.

DICOTYLEDONS.

Drimys Winteri, Forst. Original "Winter's Bark" of medicine. Temp. S. America.
Anona Cherimolia, Mill. The "Cherimoyer," an excellent fruit. Bolivia & Peru.
Berberis vulgaris, L. Common Barberry. Europe.
Chilidonium majus, L. Celandine. Europe, W. Asia.
Bocconia frutescens, L. The "John Crow Bush" of Jamaica, so called because not even the "John Crow"—the carrion bird—will eat it. W. Indies.
Isatis tinctoria, L. Woad. Gives a blue dye. Europe & N. Asia.
Linum usitatissimum, L. Flax. Affords Linseed. Europe & Asia ; not known wild.
Cytisus Laburnum, L. Several varieties. Laburnum. Europe.
——— *proliferus*, L. f. "Tagasaste." Recommended as a fodder plant. Canary Islands.
Spartium junceum, L. Spanish Broom. Europe.
Galega officinalis, L. Goat's Rue. Europe.
Colutea arborescens, L. Bladder Senna. Europe. [Minor, &c.
Ceratonia Siliqua, L. Carob Bean, "St. John's Bread." Pods a good food for stock. S. Europe, Asia
Ribes nigrum, L. Black Currant. Europe & W. Himalayas.
Cephalotus follicularis, Lab. Australia Pitcher-plant. W. Australia.
Pimpinella Anisum, L. Anise. Egypt, Creto, &c.
Sambucus nigra, L. Common Elder. Europe.

Cinchona pitayensis, Wedd. Pitayo Bark. The principal source of quinidine. New Grenada.
——— *cordifolia*, Mutis, var. Cross. Hard Carthagena bark. New Grenada to Bolivia.
——— *Calisaya*, Wedd, var. "Verde." (Christy.)
——— *Calisaya*, Wedd., var. "Morada." (Roberts.)
——— *Calisaya*, Wedd., var. (Jamaica No. 1.)
——— *robusta*, hybr., Trimen. (Jamaica No. 4.)
Remijia, sp. One of the trees affording cuprea bark. U. S. Columbia.
Eupatorium cannabinum, L. Hemp Agrimon. Europe, N. Asia.
Antennaria margaritacea, Br. Pearly Everlasting. N. America.
Inula Helenium, L. Elecampane. Europe and N.-W. India.
Anthemis nobilis, L. True Camomile. Europe.
Anacyclus Pyrethrum, DC. Pellitory of Spain. Used to relieve toothache Algeria.
Pyrethrum Parthenium, L. Feverfew. Midd. & S. Europe.
Tanacetum vulgare, L. Tansy. Europe, N. Asia.
Artemisia Dracunculus, L. Tarragon. E. Europe.
Cnicus benedictus, L. S. Europe.
Cichorium Intybus, L. Chicory. Used to mix with coffee. Europe to N.-W. India.
Lactuca virosa, L. Wild Lettuce. One source of Lactucarium, a mild narcotic. Europe
Taraxacum officinale, Wigg. Dandelion. A valuable medicine. N. Temp. regions.
Syringa vulgaris, L. Persian Lilac. E. Europe, Persia.
Borago officinalis, L. Borage. Midd. & S. Europe.
Atropa Belladonna, L. Deadly Nightshade. Europe.
Hyoscyamus niger, L. Henbane. Europe.
——— *albus*, L. S. Europe.
Mimulus moschatus, Dougl. Musk Plant. Western N. America.
Lavandula vera, DC. Lavender. S. Europe.
Salvia argentea, L. Mediterranean Coasts.
Hyssopus officinalis, L. Hyssop. S. Europe.
Melissa officinalis, L. Balm. Midd. & S. Europe. [Madeira.
Cedronella trifida, Moench. *Dracocephalum canariense*, L. "Balm of Gilead." Canary Islands and
Marrubium vulgare, L. Horehound. Europe & W. Asia.
Rheum officinale, Baill. N.-E. Thibet. Affords a part, at least, of the best officinal Rhubarb.
Rumex alpinus, L. Monk's Rhubarb. N. Europe.
Chenopodium Quinoa, Willd. The small seeds used for food in Chili and Peru; not known wild.
Araucaria Cunninghamii, Ait. var., *glauca*.
Taxodium (*Glyptostrobus*) *heterophyllum*, Brongn. S. China.

MONOCOTYLEDONS.

Doryanthes Palmeri, Hill. Palm Lily. Queensland. A magnificent plant of the Agave tribe.
Schœnocaulon officinale, Gray. "Sabadilla." Central America.
Ceroxylon andicola, H. & B. Andean Wax Palm. Cordilleras.

FERNS.

Cyathea dealbata, Sw. A handsome tree fern. New Zealand.
Todea africana, Willd. S. Africa, Australia, New Zealand.

IV.—Economic Plants.

Coffee.—Leaf disease has in no degree diminished, and the continued failure of crop during the past year has added to the difficulties of all concerned in the planting enterprise of the Colony. No combined effort whatever to prevent the disease on the lines indicated by its known nature has been even attempted, whilst the waste of money and time in local applications of "cures" has continued. As, at the same time, high cultivation and liberal manuring have become, generally, impossible from pecuniary necessities, the existing state of things, however much to be lamented, cannot be considered surprising.

A remarkably wet season, too, has aggravated the condition of the badly-nourished trees, and the low prices ruling for coffee have intensified the loss by short crops. Thus the cultivation of coffee has been in many places found not to cover expenses, and the necessity of growing other products has been more than ever forced upon proprietors.

The Planters' Association having called the attention of Government to the serious ravages of "grub" in several of the coffee districts, and requested that a naturalist might be appointed to aid the planters in devising remedial measures, I have suggested that if the Association would draw up a succinct and plain statement of the points in connection with the subject which still required elucidation, I would endeavour to obtain the opinions of a skilled entomologist of repu-

tation upon them. It may be hoped that, as nothing more is required in such an investigation besides careful and sustained observation, full and accurate information on the life and habits of these coleopterous larvæ (chiefly cockchafers) will be forthcoming from the Association. I fear, however, that with reference to any remedies that might be suggested, the same want of co-operation will be met with as in other similar cases. It is a fact that there are some gentlemen here who, in opposition to the agriculturists of every other country, maintain that these larvæ do no harm whatever, as they feed only on rootlets already diseased or decayed. It is obvious that persons guided by such notions could seriously hinder any plan that might be recommended.

Liberian Coffee has had to bear severe attacks of leaf-disease,* and rises and falls in planters' estimation, yet in suitable soils and localities it does well, and the old trees in Péradeniya (now eight and nine years old) though badly diseased show no marked diminution in their crop-bearing capacities; they are, however, regularly manured. I regret to find that it is not possible to ascertain the exports of this coffee from Ceylon, as it is unfortunately not distinguished from other "plantation" in the returns.

The gratis distribution of seedlings to native cultivators through the Government Agents has continued, and I have drawn up a short paper of simple instructions for planting and cultivation. This has been printed in the vernacular and distributed with the plants. We have at Henaratgoda far more seeds and seedlings than are applied for, and I should be glad if a more general distribution could be carried out.

Cinchona.—The enormous advance in the cultivation of cinchona fully justifies one in considering it, at present, as the foremost product of Ceylon. In some of the older districts *C. succirubra* is, on numerous estates, now completely supplanting the coffee which is allowed gradually to go out of cultivation as the former grows up amongst it. During the year ending September last, as much as 3,099,895 lbs. were exported, being an increase of 1,892,175 lbs. over that for the previous year, or considerably more than double. It has, however, to be allowed that a large quantity of inferior bark has gone into the market. The position at the end of the year may be well seen from the following, extracted from Messrs. Rucker and Bencraft's Weekly Circular dated 21st December, 1882:—

"The shipments from Ceylon are very heavy, and altogether beyond what was at present expected, but they are also somewhat deceptive. A very considerable proportion of these barks are twigs, scrapings, weak branch, &c., barks, which in bales appear important and affect statistics, but from a sulphate of quinine point of view, of little value. Also much young bark is being sent forward, and for these reasons we think that those who study the position of this market must be careful not to turn round now and overestimate the production in Ceylon.

* * * * * *

"Ceylon barks were, as usual, catalogued to be sold at market prices, and a fall of 15 to 20 per cent. was at once established. Some barks sold well, and apparently at full prices, but these were invariably barks containing a heavy percentage of cinchonidine, orders for which alkaloid had been received."

The remarks made in my report for 1880 become thus every day more and more warranted—that, so long as quinine retains its supremacy, only the rich barks can secure good prices, whilst the inferior ones must hang on hand and only be sold at reduced rates. There is little or no fear of an excess in production of bark of the best qualities here, but it is otherwise with the poorer sorts, and it is with these that *from the planting point of view* production may be overdone. On this account, in growing quinine barks planters will do well to go in for the best kinds only. Of these *C. Ledgeriana* still remains by far the most desirable, but it cannot be grown at high elevations.

It is, however, at the same time pretty evident that we are approaching the time when the almost exclusive estimation of quinine must give way before the evident advantages of employing the mixed alkaloids. The great philanthropic idea which led to the acclimatization of these trees in the East—the provision of the blessing of cheap febrifuge to a fever-stricken population—must be carried to its issue in spite of any interested efforts to delay it; the practical efficiency of the imperfect preparation made by the Indian Government, now well established, has shown the way to a vast future development of the use of similar and improved preparations. Foreign manufacturers have already appreciated the great market opening before them—(thus the Zimmer manufactory at Frankfort-on-Maine makes vast quantities of sulphate of cinchonidine for export to the United States at a price from one-third to one-fourth that of quinine sulphate)—and growers should not be unprepared for the change. This, when it comes, will not be disadvantageous to Ceylon planters with their large acreage of *C. succirubra*, the *proportional* value of which to other barks will rather be increased.

* *Hemileia* not unfrequently attacks the fruit in this species.

How great a demand for a febrifuge drug exists in the East may be gathered from the subjoined extract from a report on the trade of Kanagawa, Japan, by Consul Enslie :—

"That the consumption of quinine is not so large as might be expected is due to the fact that the bulk of the population in Japan is too poor to pay for such an expensive drug, and the cheaper cinchona alkaloids are sold in place of it. English-made quinine does not appear in this market; that principally imported is prepared in Milan. Then comes German, and after that Pelletier's muriate of cinchonine, which is imported in large quantities.

* * * * * *

"The Japanese *prefer goods of English preparation,* and if manufacturers comply with the requirements of this market it will doubtless prove to be an important outlet for their goods; it should, however, be borne in mind that they have powerful competitors in German merchants, who, in addition to their well-known scientific attainments in the manufacture of chemicals, are now turning out articles of quite as good a quality as those coming from England, and in many cases at very much lower prices."

There is also, of course, a large local consumption in this Colony, and I cannot but think that a local manufacture of mixed cinchona-alkaloids under efficient management might prove our true policy in regard to the general outlook of the cinchona industry; but the success of the enterprise depends upon a number of commercial considerations of which I am unable to judge the value.

The practice, invented by Mr. Moens, of shaving off the rich outer portions of the bark down to a plane as near the cambium zone as possible without reaching it has become very general. It is found to be simple and easily learnt, expeditious, cheap, and very convenient for drying, packing, and baling for shipment. As a consequence, it has nearly superseded other modes of harvesting, and it has been remarked that there will soon be little but renewed bark sent from Ceylon. The practice is applied to all the kinds grown, and as a rule the trees do not appear to suffer much, if the operation be carefully performed. New bark is rapidly formed, and the amount of quinine is much increased in the renewed tissues. The scraped surface is usually covered, the common mana grass (*Andropogon Martini*, Thw.), readily obtained and durable, being commonly used for the purpose; renewal, however, occurs without any covering, except in very dry weather. It is regrettable to see such very young trees (saplings of eighteen months even, scarcely three-quarter inch in diameter) subjected to this process, with the accompanying pruning off of all side branches, and the short intervals allowed between successive shavings. There is a present small gain in such procedure, but it is doubtless wasteful in the long run. I have noticed many young trees succumb to the treatment, and in any case it must greatly check their growth, impair their vigour, and shorten their life. Experiments, however, are greatly needed to determine several points in connection with this subject, especially as to the ratio of the increase of alkaloids in renewed bark to the age of the tree, the best period to allow to pass between successive shavings, &c. It is much to be desired that gentlemen who have the opportunities would carefully conduct such investigations upon their estates, and it would be in such cases that, in my opinion, the assistance of Government in obtaining the necessary analyses, for the general good, might be fairly asked for.

The bark taken from a few old trees of *C. succirubra* at Hakgala (see p. 4) was sold in Colombo in December. The trees were in all probability some of those raised from Spruce's original seed received in 1861, the young plants from which were planted out in 1863 in the wild jungle, in accordance with the views then accepted as to their requirements. Though the oldest, these were not the largest in the Island. One stem girthed 37 inches near the ground, and 24 inches at 5 feet above it; its roots were badly cankered. This tree gave 77 lbs. of wet bark (25 lbs. when dry), and most of this was fine quill. The handsome trunk bark of these trees was locally analysed (by Mr Cochrane, of Colombo) for sale purposes, and yielded 5·62 per cent. total alkaloids, 2·41 per cent. being quinine sulphate. No fuller analysis was made, and this fine bark was apparently sold on its quinine value only.*

* I am able, by the kindness of Mr. J. E. Howard, who at my request has been so obliging as to analyse a sample of the bark of the large tree above mentioned, to supply its full alkaloidal composition.

Quinine	...	2·06 (= Quin. Sulphate 2·75)
Cinchonidine	...	3·47
Cinchonine	...	0·61
Quinidine	...	Trace
Amorphous	...	0·66
Total alkaloids	...	6·80

This analysis of Messrs. Howard differs, it will be observed, considerably from that given above of a sample of the whole parcel, showing 0·34 per cent. more of quinine sulphate, and no less than 1·18 per cent. more of total alkaloids than were found by the local chemist. [*Note added.*]

The trees of *C. Ledgeriana* barked at Hakgala at the same time were small and not three years old. The local analyses of this bark showed 2·63 per cent. of quinine sulphate and 4·53 total alkaloids. A number more of these remain at Hakgala, but are dying out steadily; the high elevation (over 5,600 feet), shallow soil and wet sub-soil are insurmountable obstacles to the cultivation of this species. Taking these local disadvantages into consideration, the above analysis of such young trees is satisfactory.

Two plants of "Hard Carthagena" bark were received from Kew in September. One of these succumbed to the voyage and was dead on arrival, and the other nearly so, but Mr. Nock has succeeded in saving it, and there are now three plants at Hakgala. Several varieties of this were collected by Cross in 1878, the best at Coralis Inza, in the district of the Magdalena, at 7,000 feet elevation. An analysis of the bark by Howard showed:—

Quinine	...	1·88
Cinchonidine	...	1·18
Quinidine	...	·18
Cinchonine	...	·71
Total	...	4·75

It appears to be an undescribed species or variety, occupying, according to Howard, a sort of intermediate position between *C. cordifolia* and *C. Calisaya* with points of resemblance to *C. purpurea*. Markham refers it without hesitation (and without evidence) to *C. cordifolia*. It seems different from the *C. cordifolia* (also from Carthagena) of the Java plantations received from Mr. Moens last year.

To the Madras Government I am indebted for seeds of *C. pitayensis* received from Dodabetta in March. It germinated well. This affords "Pitayo" bark, remarkable as the chief source of quinidine. It also is a native of New Grenada (Pitayo is near Popayan) and is a remarkably distinct species with long calyx-teeth and the corolla hairy inside. Mr. Moens has analyzed* the bark of one of the Dodabetta trees, ten years old, with the following result:—

Quinine	...	2·49
Cinchonidine	...	0
Quinidine	...	2·10
Cinchonine	...	2·52
Amorphous	...	0·58
		7·69

It is thus seen to be a valuable species, and is said to be very hardy.

Seed of two sorts from Jamaica has been received through Kew,—of the "Jamaica hybrid," which appears quite the same as the hybrid *robusta glabra* of Ceylon (whence the seed was probably sent), and of "*Calisaya* No. 1," which is just an ordinary sort of no special value.

Several varieties of "*C. Calisaya* alleged to be of first-rate importance have been recently obtained direct from South America. I am indebted to Mr. J. C. Roberts, of Udagama, for a little "morada" seed lately received by him. This was sent to Hakgala in September, and there are over 200 seedlings, but Mr. Nock thinks it too cold for them there. To Mr. T. Christy, of London, we owe seed of the "verde" variety from Bolivia (received in February), and this germinated well. Mr. Holmes, of the Pharmaceutical Society, matches the leaves with the var. *oblongifolia* of Weddell. Of both these it is as yet too soon to pronounce as to their type, whether mere calisayas or the much more valuable, and as I think quite distinct, *C. Ledgeriana*.

After much trouble, seed has been obtained at Kew of the "Cûpra Quina" tree affording the "Cuprea" bark imported during the last two or three years to the London market (*viâ* New York) in such vast quantities. A little of this seed has been sent to me; it was collected from trees growing between 5,000 and 6,000 feet at Landasugi, in the State of Santander (U.S. Columbia), and sent from Bogota. No time was lost by me in forwarding this to Hakgala, but I regret to say that only two seeds germinated, of which one subsequently died, so that we have now but a single seedling of this interesting plant. Mr. Triana has identified the Cuprea-bark trees as species of *Remijia*, a genus nearly allied to *Cinchona*, so that it is no longer possible to consider the febri-

* Quarterly Report of Java Cinchona Enterprize; July, 1881.

fugal alkaloids exclusively produced by the latter.* The analyses of the better sorts of Cuprea bark average 1·8 to 1·9 of quinine sulphate, rarely reaching 2 per cent. ; but some varieties are almost worthless. Manufacturers, however, prefer it in consequence of its freedom from cinchonine and the readiness with which it pulverizes. There are many varieties, and some grow at a much lower elevation than that above given ; it is thought such may do in low coast districts.

Tea.—The past year has witnessed a very striking rise in the export of tea,—no less than 345,702 lbs. more in the year ending September, 1882, than in the previous one, the whole quantity shipped being 623,292 lbs. Tea estates have been opened at all elevations, from near sea level up to the highest available land in the wet districts, and many old coffee estates, not suited for cinchona, are now cropped with tea. This article has thus stepped into the second place, and with cinchona has gone a considerable way towards compensating for the serious diminution in coffee.†

In connection with tea, I may mention that an excellent wood for boxes is that of *Cedrela Toona*, a large tree with a wide geographical range in Tropical Asia, but not native to Ceylon. The few trees in the gardens give an abundance of seed, and it has the advantage of growing very quickly. Thus seedlings at six months measure 10 feet high, and in trees seven years old the circumference of the stem one foot above the ground is 4 feet 10 inches. The wood is light, strong, clean, non-resinous, and not attacked by insects.

Cacao.—There is every prospect that this article will play an important part in the future of Ceylon cultures. The year ending with September, 1882, saw 1,018 cwts. exported, against 479 cwts. in the previous one; and what is more satisfactory is that the prices secured show that our product is of the best quality and esteemed in the market. In the lower hill districts are many old and more or less abandoned coffee estates, and on not a few of these cacoa is being successfully grown, if only due care be taken in first planting, and protection from wind afforded during the first two years.

Several enquiries have been made of me as to the variety to which this old Ceylon cacao—which has now shown itself of so good a quality—ought to be referred. Its origin in Ceylon is quite obscure ; it was in cultivation in Moon's time (1824), and has probably been continuously grown in the botanic gardens since that date. The cacao of the Dumbara Valley estates (which is that chiefly exported hitherto) appears identical with the old untended and semi-wild trees in Pérádeniya. This I have been accustomed to refer to the class of cacao called " Forastero" in the West Indies, and probably it may be the variety called " Red Condeamar," which is one of the best sorts. Its fruit is always dark red, and the section of the ovoid scarcely compressed seeds (like large almonds) is yellowish-white, becoming darker on exposure.

In recent years several other kinds, with paler pink or yellow fruit, have been imported into Ceylon. Of these, some were introduced in 1873 by Mr. Worms, and others by Captain Bayley, the Ceylon Company, &c. Some were obtained direct from Caracas, and consequently the plants have been generally known as " Caracas" in the Colony. Several varieties of this sort are in the Henaratgoda Gardens ; the pods vary in colour, pale glaucous green passing into yellow or orange, pale pink or pale crimson, and the seed is always flattish, and paler or darker purple in section. It is clear that the true " Caracas"—also known as " Criollo"—(creole) cacao is a different variety from these, as it is stated to have the pods almost invariably red and the seeds *nearly globular* and *pale crimson on section.* I am thus inclined to refer our pale-fruited kinds to the varieties called in Trinidad " Verdiliço" and " Cayenne," the former with the long-pointed worted dark yellow or orange fruits, and the latter with the pods smoother and blunter. But these determinations are little more than reasonable guesses.

Comparison will, however, soon enable us to check and correct them, as examples of these last and other sorts were received from Trinidad two years ago.—(See previous reports). Among them are also some true Criollo, the fruiting of which I shall watch with interest : so far as I can judge, with the exception of these, there is no true Caracas cacao in this Colony.

A further gratis distribution of seed has been made to native cultivators.

India-rubber.— In continuation of my previous reports on the South American rubber-trees, I have now to record a considerable step in advance. Samples collected from each of the three species have been submitted to the best commercial authority in London, and the reports received

* This consideration should encourage search among allied plants, even in the Old World ; but only analysis can decide as to real value. Mr. Low, of Perak, has recently sent me leaves of a tree thought by some there to be a " wild cinchona"; it appears to be a species of *Wendlandia*, but I have heard nothing of its properties.

† The fine unpruned trees of " Assam Hybrid " in Pérádeniya are now 16 years old (having been obtained from India in 1867); they yield a fair quantity of seed, which is, however, now rarely applied for.

are very encouraging so far as the quality and value of the product is concerned. In no way does the rubber fall short of that from the wild trees.

A tapping of Ceara (*Manihot Glaziovi*) was made at the end of April (dry weather) and about 20 ozs. of dry rubber were obtained from nine or ten trees. One of these afforded nearly 4 ozs., whilst another, which had been bled to the extent of 2 ozs. the year before, gave scarcely 1 oz. The process followed consisted merely in peeling off the dry parchment-like outer bark and making short slanting cuts with a sharp knife on the green surface exposed. The milk flowed most freely in the early morning. I at first experimented with a small axe purposely constructed with a sharp cutting edge prevented from penetrating too deeply by a projecting shoulder, but this did not answer so well as an ordinary knife. The milk which trickled down the stem was allowed to remain there till it solidified, when the strings were pulled off and rolled into balls. By this means a generally clean and dry sample was secured; a portion, however, afterwards acquired a somewhat sticky consistence along with a slight admixture of sand contracted by dropping on to the soil at the foot of the tree. I separated this from the rest and submitted both to Messrs. Silver for report, in June. They valued the dry and clean portion at 2*s.* 9*d.* to 3*s.* per pound—a high price for "Ceara Scrap"; the sticky portion, which could not be properly washed and analyzed, was not considered worth more than 1*s.* to 1*s.* 3*d.* per pound. The importance of taking care to secure a clean, dry rubber is thus very evident.

The value of Ceara rubber being now assured, it may be expected that planters (some of whom have now a large stock of trees) will institute experiments as to the method which will secure the largest quantity of milk per annum or during the life of the tree.

Further supplies of seed have been sent to the Gardens and Forest Departments at Saharunpore, Lucknow, Assam, British Burmah, Bombay, Perak, and Jamaica.

The *Castilloa* trees both at Pérádeniya and Henaratgoda have flowered during the year, but a single tree only (at Pérádeniya) ripened any seed. Two fruits were matured in June from which 15 seeds were obtained; of these 9 germinated on the thirteenth day after sowing, and have grown rapidly. It is hoped that a larger quantity will be produced during 1883. The trees are now six years old; the largest at Henaratgoda is about 46 feet high and 26 inches in circumference at a yard from the ground, an increase of 3½ inches in girth during the year.

A few plants have been sent to India in 1882, viz.:—to Ootacamund 2, to Calcutta 2, and to Nilambur 3; and I am about to despatch 6 more to the Malabar Coast.

Hevea has not yet flowered at Pérádeniya, and I am disappointed that only 36 seeds were secured at Henaratgoda. In Mr. Low's experimental garden at Perak several trees have seeded, and to his courtesy I am indebted (through Mr. J. A. Swettenham) for 18 seeds, but they were all quite dead on arrival, in March.

The plantation at Henaratgoda has been thinned out in the hope of more sunlight leading to a larger production of flowers. Our largest tree there is now about 50 feet in height, and at a yard from the ground measures 25½ inches in girth, 4½ inches more than last year.

I regret that no information has reached me as to the safety or otherwise of the case of 28 plants of *Hevea* sent to the Andaman Islands in November, 1881.

An experimental bleeding of both *Hevea* and *Castilloa* was made at Henaratgoda in October. Five of the *Hevea* trees were prepared by scraping off on one side the rough surface of the outer bark; a few short cuts with a knife were then made and the rubber allowed to dry (as in the Ceara): the strings were rolled off into a ball, which weighed somewhat over 2½ ozs. Only two *Castilloa* trees were slightly bled in the same way, the sample ball obtained weighing above 3 ozs. Both samples were perfectly clean, and were forwarded to Messrs. Silver for report in November.*

* This (dated 8th December, 1882), was received in January, 1883. The *Hevea* rubber was found to differ chemically in no respect from the better descriptions of Para bottle rubber, but the ash was about one-half only. "As far as can be determined on so small a sample, there is reason to believe that as regards strength and elasticity it would be fully equal to good Para India-rubber." The market value was estimated at 4*s.* per lb.

The *Castilloa* sample was found to become on drying much darker and shorter than the Para. This shortness "would restrict its use to some slight extent where tensile strength or tenacity is required. When mixed with the usual proportion of sulphur and heated, it vulcanizes well, but imperfectly, and is devoid of strength—characteristics of the better kinds of rubber. Nicaragua rubber is not at present met with in this country to any great extent, but there is no doubt that the purity and general qualities of this sample would gain for it a favourable reception even if our supplies from present sources were more adequate to our demands.

The chemical analysis of the ash of the Castilloa shows that there is no very marked difference in the mineral constituents of the pieces of the Hevea and Castilloa under the present system of cultivation."

This is most encouraging, and it may be expected that the Indian Governments will be stimulated by it to seriously take up the cultivation of the American rubber trees.—[*Note added.*]

No new kinds of rubber-producing plants have been received in the past year. The "apocynaceous" rubber sent out by Mr. T. Christy recently (see his "New Commercial Plants," IV., p. 13), has flowered, and proves to be a *Cryptostegia*, probably not distinct from *C. grandiflora*, a common plant in Colombo gardens. It is therefore not "apocynaceous," but asclepiadeous. The species was long ago advocated in India as a rubber-yielding plant, but the quality of the product remains to be tested.

All the climbing caoutchouc plants—*Landolphia* (including *Vahea*), *Urceola* (including *Chavannesia*) and *Willughbeia*—grow very much better at Henaratgoda than in the Pérádeniya garden, which is at too high an elevation for them ; *Landolphia florida* succeeds best in the latter locality. *L. Kirkii* makes but slow growth here compared with Henaratgoda, where the stem of one (now nearly three years old) is fully three-fourths of an inch in diameter. The milk of this species I find to be extremely thick, solidifying with rapidity into a very tough, elastic rubber ; it should be a very good sort, but will be difficult to collect. The *Urceola* (*Chavannesia*) *esculenta*, which completely failed at Pérádeniya, has made astonishingly rapid growth in the tropical garden, where in the course of a few months it has completely covered trees of considerable size with its long close-twining stems. I may mention that the leaves of our plant are thin, dark green, and roughly scabrous-pubescent on both surfaces, thus differing greatly from the description of *U. esculenta* in the recently published "Flora of British India": it has not yet flowered. Mention of this book reminds me to note a slight change of nomenclature. The *Willughbeia Burbidgei* of the Kew Report for 1880 (and mine for 1881) proves to be identical with a species already described, *W. firma* Bl., found also in Sumatra and Borneo. Also, I find that the plant in Pérádeniya sent by Mr. Murton from Singapore some years back (and which I had not previously distinguished from the last) is *W. flavescens*, Dyer (*Chilocarpus* in Kew Report, 1880). Both these species seem to afford the "Gutta Singgarip" of Singapore.

Seeds of *Hancornia speciosa*, the Mangabeira rubber, have been received from Kew and from Mr. T. Christy, but none have germinated. The *Tabernæmartana crassa* seedlings have also died off at Pérádeniya, but one plant at Henaratgoda is doing well.

Gutta Percha.—The "Gutta Sundek" trees (*Payena*, sp.) are doing well ; naturally, they grow more rapidly at Henaratgoda, where the largest are now 3 feet 9 inches high. I have not as yet been able to get any nearer to the name of this tree. Prof. Oliver, of Kew, to whom I sent specimens, is inclined to refer it to *Payena* (*Keratephorus*) *Leerii* (Hassk.), in which M. Beauvisage, of Paris, agrees, but Mr. Clarke, in the new "Flora of British India," thinks this an erroneous determination.

I am again greatly indebted to Mr. Low, of Perak, for seeds of a second Gutta Percha tree. These were received in September, germinated well, and are now promising seedlings. These were sent under the name of "Gatah taban putih," but Mr. Low has since expressed some doubt as to this source. They are however clearly from a species of *Dichopsis* (or Bassia?). To judge from the leaf-specimens of "Gatah taban putih," afterwards sent by Mr. Low, this can scarcely be separable from *D. Gutta ;* the leaves are somewhat broader, and their primary veins more prominent than in that species. Mr. Low writes with them : "This is the most common of the species of Gutta Percha, but I have never been able to find it in flower ; it is a very large tree."

There still remains the best sort—"Gatah taban merah"—of these Gutta trees to be collected, and Mr. Low is energetically endeavouring to secure the seed of this also.

Medicinal plants.—It is my intention to cultivate such of the plants used in medical practice in the Colony as will grow well in Ceylon, and especially to devote a part of Hakgala garden to this object.

Jalap.—Mr. Nock reports as follows :—"The half-dozen plants here have been increased to about 150, which are now in a very healthy condition, and promise to do well." I hope next year we may be able to send home some samples for report.

Taraxacum.—This valuable drug is largely used in the Colony, and it would be very advantageous to have the fresh root at hand. A supply of seed was obtained from Saharunpore in April, and was at once forwarded to Hakgala. Mr. Nock has taken much pains with its cultivation, and sends the following report :—"Small plots were at once sown in five different places. Of those sown in patana land, in an old tea clearing, and in a poor place in an abandoned cinchona plantation, scarcely a plant grew further than to make two leaves. Their death was partly due to the great heat of the sun for a few days just after they germinated, and partly to the poorness of the soil. The seed sown under shade, and that on rather better soil and in a damper situation, came up well, and the plants are now looking very healthy and promise to turn out well. A portion

of the seed was sown in nursery beds under thatch. All this germinated well, and when the seedlings were large enough to handle they were pricked out. Some were planted on the plots of land where the seed had failed, but these also failed to thrive, and the poorness of the soil is shown by the plants being hardly any bigger now, after several months, than when pricked out. The old tea clearing, which is about half an acre, was also prepared and plants were pricked out in this 3 inches apart. They are now all established and are growing well, and should be ready to lift in three or four months' time. 274,000 taraxacum plants were pricked out in the above-mentioned places."

The want of depth of soil and its poverty in nitrogenous matters are no doubt against the production of the finest roots, but I am glad to see that some roots have already attained the very creditable length of 14 inches, and I believe that, with some manuring, a satisfactory product will be secured.

Other drugs established at Hakgala are Rhubarb (both the official species), Belladonna, Hyoscyamus, Digitalis, Camomile, and others, some of which it will be probably worth while to grow for use in the Colony.

Seeds of *Guaiacum* or *Lignum Vitæ* were received from Jamaica, and have grown well; a small plantation of this has been formed at Pérádeniya.

Chinese Cassia lignea.—To Mr. Ford (Superintendent of the Botanic Garden at Hongkong) the Gardens are indebted for sending (with the consent of the Secretary of State and the Government of Hongkong), a Wardian case of young plants of *Cinnamomum Cassia*, the plant affording the "Cassia lignea" of commerce. Eighteen of these have been planted at Pérádeniya, and some sent to Hakgala for trial. The plants seem very hardy. These were collected by Mr. Ford himself from the plantations on the West River in the province of Kwangtung, South China, where an immense cultivation is carried on. Like our Ceylon cinnamon, the precise plant is not known wild, but is probably a cultivated race of some common wild species. By this visit Mr. Ford has satisfactorily determined that this is the sole source of "Cassia lignea," which has been hitherto supposed to be derived from a number of species of *Cinnamomum*. Dried specimens kindly sent me at the same time show that the species is quite the same as the *C. Cassia* figured by me in "Medicinal Plants," tab. 223, which was drawn from dried specimens at Kew collected by Dr. Hance from a tree (as I have since ascertained) growing in the Public Garden of Canton. The export of this product from Canton in 1878 reached the enormous quantity of 58,313 piculs; it is, however, of far less value than cinnamon in the market. The spice has been brought from South China since the earliest dawn of history, and is doubtless the original cinnamon of the Mosaic and other early writings. The scent of the leaves is far more pleasant than that of Ceylon cinnamon. A return case of the latter has been sent to Hongkong.

Star Anise.—Some seeds of the true Chinese "*Star Anise*" (*Illicium anisatum*) have been received from Dr. Hance, of Whampoa, but, I regret to say, all failed to germinate. (This was also the case with some kindly given me by Mr. C. J. Scott in 1881.) They were obtained by a special agent in the south-west of Kwangsi from the living trees. This fruit is a large export from Pakhoi, one of the less-known treaty ports of China, but the Chinese always take care to *bake* it before export, so that the tree is unknown out of the country.

Borneo Camphor.—I have had another disappointment in the failure to germinate of seeds of a very interesting plant—the camphor tree of Borneo and Sumatra (*Dryobalanops aromatica.*) After a good deal of difficulty, Dr. Treub, Director of the Buitenzorg Gardens, succeeded in obtaining these seeds from Sumatra, but all were quite dead before reaching Ceylon. This magnificent tree is in no way allied to the ordinary camphor; its product is wholly consumed in China and Japan, where it fetches a price equal to £4 or £5 per pound, and consequently never finds its way into European commerce.

"*Mysore*" *Cardamom.*—In my last report I mentioned under this name a variety of the ordinary *Elettaria Cardamomum*, differing merely in having the raceme of flowers carried up from the base to the summit of the leafy stem, an accident which occurs occasionally in other allied species of Zingiberaceæ. I now find that I was misinformed as to this being the variety known by planters here as "Mysore" cardamom. That plant presents differences other than the one above noted. These are the following, so far as I have yet been able to observe:—the leaves are distinctly stalked, the petiole being about one inch long; the blade is broader than in the Malabar form, and quite smooth (not pubescent) beneath, and the ligule is decidedly larger; the flower-raceme comes off from the usual place—the base of the leafy shoot, but is stiff and erect, instead of prostrate, on the soil. I have not had an opportunity yet of examining the flowers or fruit. It is clearly a

well-marked variety, and can be recognized when a small seedling. The plant is larger and more robust, and is said to thrive at a higher elevation than the ordinary kind.

Pepper.—As the cultivation of this condiment is attracting some attention in the Southern Province, I have been at the pains to obtain from Singapore some roots of the best sort there grown. These only arrived towards the end of the year. They are growing vigorously, and will be cultivated in the Singapore manner. *Erythrina* stumps have been planted for the support of the "vines." The foliage of these plants appears at present to show considerable differences from any of the peppers grown by the natives here.

Cow Tree.—The specimen of *Galactodendron* at Henaratgoda is 18 inches high, and flourishing. Of the two at Pérádeniya, always sickly, one succumbed to the prolonged wet weather and the other was destroyed in a night by a hare, which nibbled it off down to the ground.

Sago.—The young plants raised from the Sarawak seed all grew vigorously, but there has been no demand for them. A small artificial marsh was made at Pérádeniya and 27 plants put out in it at eight feet apart. These have made splendid growth and are perfectly healthy.

Wax Palms.—The Brazilian Carnauba palm (*Copernicia cerifera*, Mart.) has been introduced to the Colony by private means. I am indebted to Mr. W. Ferguson, of Colombo, for seeds which germinated fairly, and we have now numerous young plants. The wax in this species comes from the young leaves in the form of a scaly powder.

The wax palm of the Andes, *Ceroxylon andicola*, H. & B., is one of the few mountain palms flourishing, with oaks and conifers, between 8,000 and 10,000 feet in the Cordilleras. The wax here is an excretion from the trunk between the leaf-scars. Seeds of this interesting plant were received from Kew, and the young plants are doing well at Hakgala.

Orchella Weed.—This figures as a rather large export from Ceylon, the amount in the year ending September, 1882, being no less than 1,157 cwts. As I have had several inquiries about it, the following information may be of use. The plant is a lichen, and grows in the hot dry districts of Ceylon close to the coast, or at least not beyond maritime influence. Its favourite localities are seashore rocks, where on the east coast it is frequent, but it is also commonly found on old tree-trunks near the coast, as about Jaffna. The species appears to be *Roccella Montagnei* only, no other member of the genus, so far as I know, occurring in the Island. It is a pale greenish-grey lichen with the fronds ribbon-like, flaccid, much and irregularly cut, torn and split-up. The colouring matters Litmus (solid), Orchil (liquid), and Cudbear (a powder) are manufactured from this and other species.

Peruvian Cotton.—Mr. J. C. Roberts, of Udagama, has sent seed of this kind of cotton from Peru. It is very favourably noticed by Mr. Markham (in his work "Peruvian Bark"), who introduced it into India, where he says it has been "highly spoken of by the agriculturists of Madras." It is said to be the only long-stapled sort that will endure prolonged dry weather, and should therefore be very suitable for our northern districts. I have sent some to Anurádhapura, Vavúṇiyaṉ-Vilánkulam, and Mannár for experiment.

Fibres.—In view of the large amount of land formerly under coffee but now uncultivated, it becomes a question whether some one or more of the numerous fibre-yielding plants might not be grown with profit. Of these the large green aloe *Fourcroya gigantea*, formerly *Agave fœtida*) so commonly grown for hedges in the coffee districts, and the less frequent glaucous-leaved one (*Agave americana*)—both long ago introduced—as well as the pine-apple and the plantain, yield excellent fibre and are abundant. Of others, such as Rheea, Ramee or China grass (*Boehmeria nivea* and varieties), Manila hemp (*Musa textilis*) and New Zealand flax (*Phormium tenax*) the gardens always keep up a small supply which can be readily increased if needed.

Many of the native fibres might be also worthy of trial on a large scale. The following are the most promising:—Belli (*Hibiscus tiliaceus*), Jute (*Corchorus capsularis* and others), Caleya (*Grewia* species), Hanna, Sunn hemp (*Crotalaria juncea*), Wara (*Calotropis gigantea*), Dul (*Boehmeria malabarica*), Allandu (*Allœanthus zeylanicus*), Neyanda (*Sanseviera zeylanica*); and a true Aloe (*Aloe indica?*) which grows on the sea coast in the dry districts.

Forests.—It is a matter for satisfaction that the whole subject of the future management of our remaining forests can scarcely fail to be raised on the Report of Mr. Vincent, who is now concluding his labours in Ceylon. In the present condition of the revenue too much care can scarcely be bestowed on this subject, and it may be hoped that the reform so urgently needed in the careless waste and want of management of the past will be a thorough one. It does not fall within my province to enter on this important subject, which is beset with difficulties, but there are some cognate matters which I would wish to press upon the attention of Government. Apart from

the demarcation and conservancy of natural forests, there is a large field for enterprise in the systematic formation of plantations of timber trees. Teak can be grown over large portions of the Southern, Western, and Central Provinces, and sandalwood in the drier parts of the last mentioned. In different ways these are the most profitable woods known. But there are other substances besides timber yielded by forest trees which are not suited for private culture. Such are most of the India-rubbers, especially *Hevea* and *Castilloa*, and such even more markedly are the gutta perchas, for which a large demand must arise before long. These products appear to me eminently suitable for cultivation by a Forest Department as a source of revenue. The utilization of waste lands should also be considered in this connection, either in the way of re-afforesting where possible, or by the cultivation of other products, such as some of the fibres above alluded to, or others suitable for paper-making.

V.—Herbarium and Library.

Herbarium.—The arrangement of the herbarium of Ceylon plants has been completed during the year. The specimens are now mounted on thick white paper, properly arranged and nearly all written up; the collection is thus in perfect order for reference. Numerous additions have been laid into their places. During this work, which has engaged much of my time, a number of extra specimens have been removed from the herbarium, forming a fair series of authentic duplicates; these I am about to send to Hakgala for the Superintendent's assistance in learning the names of the native plants.

I made two expeditions for collecting during the year, one to Horton Plains, Bilhul-oya, &c., the other to Hambantota, Kirinda, and the neighbourhood. The latter little-known district afforded me over twenty species previously unrecorded from Ceylon. I have to thank the Government Agents and Assistants for their kind aid in furthering my objects.

The general herbarium is making good progress. The plants are now arranged in their genera as far as to the end of the monopetalæ, nearly two-thirds of the whole. Four new cabinets have been set up towards their accommodation.

During my visit home I was permitted by the Director of Kew Gardens to select a number of duplicate sets of plants from the herbarium, and these have since been received here. They comprise plants from Algeria, collected by Munby; from Sikkim, by Treutler; from the Malay Peninsula, by Griffith and Helfer; from Formosa, by Oldham; from Fiji, by Horne; and from Brazil, by Glaziou; also a portion of the late General Munro's herbarium, and a set of cinchonas from the Nilgiri plantations collected by Dr. Bidie.

To Mr. C. B. Clarke, of the Bengal Education Department, I am indebted for a set of duplicates of part of his large Indian herbarium.

Little progress towards a *Museum* of vegetable economic products, &c., has as yet been made. I find that this climate requires that all specimens be preserved in close glass-stoppered bottles, or they rapidly fall a prey to damp, mould, and insects. The expense of these it has hitherto been impossible to afford. I am, however, bringing together specimens as opportunity occurs, and fully intend to get this useful adjunct to a botanic garden into proper shape as soon as possible. I take this opportunity of saying how gratefully I should receive suitable specimens towards this collection.

Library.—Many valuable books have been acquired during the year. Of these, several were presented by the executors of the late Dr. Thwaites (whose lamented death occurred on the 11th September), and in addition to the books is a valuable series of original drawings. These consist of dissections of the flowers, &c., of Ceylon plants by Dr. Thwaites, and represent much of his work in our native flora upon which the "Enumeratio" was based. This series has been placed in the herbarium and is available for use by students of Ceylon botany along with the dried specimens themselves.

The following have been the additions to the Library during the year:—

Triana, Recherches nouvelles sur les Quinquinas, 1870.
Veitch, Manual of the Coniferæ, 1881.
Clarke, C. B., Commelinaceæ et Cyrtandraceæ Bengalenses, 1874. (*Presented.*)
Treub, Annales du Jardin Botanique de Buitenzorg, Vol. II., Part 1, and Vol. III, Part 1, 1881–2. (*Presented.*)
Beccari, Malesia, Parts 2 and 3, 1877–8. (*Presented.*)
Hooker, J. D., Students' Flora of the British Islands, 1870. (*Presented.*)
Hooker and Baker, Synopsis Filicum, Ed. 2, 1874.
Mitten, Musci Indiæ Orientalis, 1859. (*Presented.*)

Muller, C., De Muscorum Ceylonensium coll. Neitner, 1868. (*Presented.*)
Harvey, Nereis Australis, Parts 1 and 2, 1848–9. (*Presented.*)
Cooke, M. C., British Fungi, 2 Vols., 1870–1. (*Presented.*)
Ward, H. M., Morphology of Hemileia vastatrix, 1882. (*Presented.*)
Brown, R., Miscellaneous Botanical Works, 2 Vols. and Atlas, 1866–8. (*Presented.*)
Darwin, C., The Forms of Flowers, 1877. (*Presented.*)
Ford, C., Report on Cassia lignea, 1882. (*do.*)
Neitner, The Coffee Tree and its enemies, 1872 (*do.*)
The Planters' Gazette, 1882. (*Presented.*)
Linnean Society's Journal—Botany, 18 Vols., 1857—81. (*Presented.*)
Gamble, Manual of Indian Timbers, 1881. (*Presented.*)
Moore, F., Lepidoptera of Ceylon, Parts 3, 4 and 5. (*Presented.*)
Hooker, Icones Plantarum, Vol. XIV., Parts 3 and 4 (in continuation).
And numerous memoirs, papers and pamphlets.

Also the numbers for the year, in continuation, of the following periodical publications :—
Belgique Horticole, Botanical Magazine, Botanische Zeitung, Gardener's Chronicle, Flora, Indian Forester, Nature, Pharmaceutical Journal, Journal of Botany and Tropical Agriculturist.

We have also received the usual Annual Reports of Indian and Colonial Botanic Gardens, Forests, Cinchona plantations, &c.

VI.—Receipts from Sales.

The sales of plants and seeds have been considerably less than in 1881, the Gardens especially suffering from the general depression and want of ready money.

The following are the receipts paid to the Treasurer during the year :—

		Rs.	cts.
From Pérádeniya	...	2,916	17
Henaratgoda	...	487	39
Hakgala	...	166	75
Total...	Rs.	3,570	31

against Rs. 4,938·32 in the previous year.

The sale of Hakgala bark at Colombo produced, clear of all charges, Rs. 959·26, making the total receipts up to Rs. 4,529·57.

In the *number of purchasers* the diminution is still more evident—

At Pérádeniya	...	489
Henaratgoda	...	130
Hakgala	...	39
Total		658

against a total of 1,147 in the year 1881.

VII.—Expenditure.

The total expenditure on this Establishment for 1882 has been Rs. 37,824·58, divided as follows :—

		Rs.	cts.
Salaries	...	17,798	25
Gardeners' and Labourers' Wages :—			
Pérádeniya (Revenue Service)	...	8,181	73
Hakgala (do.)	..	3,000	00
Henaratgoda (do.)	...	1,999	41
Pavilion, Kandy (Miscellaneous)	...	2,173	75
Office Contingencies ...	...	2,598	64
Stationery (Revenue Service) ...	...	74	66
Travelling and Collecting (Transport)	...	1,998	14
	Rs.	37,824	81

HENRY TRIMEN, M.B.,
Director.

Pérádeniya, 1st January, 1883.

The Tank Plants at the Government garden a Rangoon suffer from a strange enemy. The lakes in the gardens are infested with tortoises, or fresh-water turtle, which have gradually destroyed all specimens of the *Victoria regia*. The last specimen was preserved for a long time by placing bamboo network all round it, but at last, when the lakes filled during the rains, this could no longer be done and it too was destroyed.—*Englishman*, 14th March.

Tapioca from Haputale.—We have been favoured with samples of tapioca and of tapioca flour grown and prepared in the country. The tapioca may not look quite so white as that imported usually from England, but we fail to perceive any difference between the two when cooked, and should certainly use island-grown produce on principle if it were put into the market. The flour seems to resemble arrowroot, but it has more body and flavour and seems more nutritious. If cheaper than corn-flour, it might well take its place for household use. Mr. Westland, who sends us the samples does not seem to consider the preparation of it very troublesome. He writes:—"I think it a pity more do not go in for cultivating this useful article of food, not so much for export as for private use. The root, when divested of the woody top, carefully cleaned, cut up into pieces and boiled, is a grand substitute for potatoes. The refuse of the root, *i.e.*, when all the flour or starch has been extracted, is readily eaten by cattle, and I imagine has about as much nourishment as poonac."

Jamaica Labourers leaving for the Panama Canal is the burden of two paragraphs in *Gall's News Letter*:—"Still they go" is the cry which we have to reiterate in respect to the labourers from amongst us who are leaving by the hundred for the Isthmus of Panama. Week after week fresh bands are emigrating Even from the other West Indian Islands, Agents have been sent to collect them, so that in course of time if this exodus continues we shall be losing a few thousands of our able-bodied labourers. Several estates are already complaining of scanty labour on that account, but the remedy to retain them, which is increased wages, is not forthcoming. 32 labourers from St. Lucia and 38 from Barbados are among the passengers *en route* to the Ishmus, engaged for one year, at the end of which term, they are entitled to return to their respective colonies at the expense of the company. The wages offered are ten cents per hour for a working day of ten hours. [In other words $1 or 4s 2d per diem! No wonder if the negroes of the West Indies are attracted.—Ed.]

Manure Heaps.—The following wrinkle may be of use to planters who have jungles adjoining their coffee. A piece of jungle is cut down and the leaves are allowed to decay; in a few months the stumps of the trees grow vigorously again. The jungle is cut down again, and after it has decayed somewhat, coolies are allowed to help themselves to the twigs for firewood, and then after the whole surface had been strewn over with lime, put to collect the leaves and top-soil into heaps. These heaps after a time are mixed with lime and fish and applied to the coffee, and the effect it is said lasts for 3 years. A piece of jungle will yield manure periodically. A Government irrigation stream runs along the bottom of Mr. Holloway's Estate, and is lined with large trees. He has the upkeep of as much of it as runs through his property. He makes *this* yield him manure. During dry weather like the present it is cleaned up, and along its whole length I observed heaps made of the weeds growing in it and the rich mud and decayed leaves that had settled at its bottom. These are made the basis of compost heaps.—*Cor.* "Ceylon Examiner."

Cinchona Cultivation in Coorg.—Fully twenty years have elapsed since the Government initiated on a small scale the cultivation of cinchona in Coorg; now that its cultivation may be fairly regarded as beyond its experimental stage, and found to be a profitable undertaking, we find several private parties coming timidly forward to renew the experiment. Land for the purpose is being sold at the surprisingly low upset price of two rupees per acre, and seeds and plants are being distributed either gratis or sold at a nominal price, so that ere long we hope to see the Government entirely relieved of its illegitimate work of cinchona planting and the enterprize entirely in the hands of private capitalists. *Bangalore Spectator*.

Coconuts on the Ceylon Seaside.—Your correspondent, who writes on the subject of coconut property along the seaside line, seems a bit of a wag from his pretending not to understand that it is the *bungalow* at Dehiwala, and not the coconut trees, that is to let. As regards the poor specimens of coconut trees along the sea-side, the poverty of the soil is the cause. What can we expect from mere *sea-sand*, on which even a blade of grass will not grow? Manure these trees with *cabook earth* and the result will be marvellous.—*Cor.* [Are our correspondents aware that so late as 1740 nine-tenths of the land between Colombo and Kalutara, now we suppose one continuous grove of coconut and other fruit trees, was described as waste land, and Governor Van Imhoff in that year surveyed and distributed the land in limited portions to persons who would plant coconuts. It is therefore possible that some of the trees along the seaside are 140 years old?—Ed.]

Sago and Tapioca.—Somebody, not content with our morning contemporary's having made such a fool of himself about Lady Florence Dixie, has evidently been hoaxing him about the preparation of sago and tapioca, for in a recent issue he says in reply to the enquiry of a correspondent about these products:—"The enquiry of a correspondent relative to these two products is easily answered. Cassava flour is the produce of the root of the manioc, which is scraped and roasted the same as is done with arrowroot, but tapioca is the produce of the sago palm, made from the flour, much as is sago, but by a somewhat different process." Arrowroot flour is made by scraping or pounding the root and extracting the starch by washing, but the flour is *not* roasted. Cassava flour is made by cutting the roots of the cassava or manioc into slices about as thick as a five-cent coin, drying them in the sun till they become brittle, pounding them in a mortar, and then sifting the powder to separate the woody from the farinacious particles. Cassava flour is not, so far as we know, a commercial product, but that is the way it is made in this country for domestic use. Tapioca is also obtained from the cassava root and not, as the *Times* in his wisdom supposes, from the sago palm, which is the tree from which sago is obtained. The starch from which both sago and tapioca are made is obtained in the same way as arrowroot flour—that is, by separating the starch from the woody fibre by washing in water—and the raw starch is in both cases in fine powder in the raw state and is made to granulate by heating it on iron plates over a fire. The name of arrowroot is derived from the use of the plant by the savages of South America as a real or imaginary medicine for wounds made by their poisoned arrows. There are two kinds of cassava, one poisonous and the other not, but the leaves of even the harmless kind are sufficiently poisonous to poison cattle if they are cut and given to the animals, as we know from experience. Yet, for some reason which we cannot explain, cattle seem to suffer no harm from browsing on the leaves of the growing plant, as we have often known them do it with impunity. The poisonous cassava is not a safe article of diet, but it is not poisonous where sufficiently cooked, because the poison in it is volatile, and can be quite expelled by heat. Tapioca can be made from either variety of the plant, but the poisonous kind is said to yield more starch than the other. Cassava will grow in very poor soil, and the quantity of tapioca that this country could produce is practically unlimited, but the demand for it is not very great.—Ceylon "Catholic Messenger."

TEA CURING.—Under favourable circumstances drying machines may do all that is promised by their vendors, but we contend that in dull cloudy weather the results expected are considerably more than can be attained; and we would ask the Calcutta houses largely interested in the industry, to bear this in mind and make a liberal allowance in their estimates for extra fuel. Did they do so we feel confident the result will be satisfactory to all concerned. In these days when one planter is pitted against another to turn out his tea at the lowest rate, we consider that such instructions as sometimes emanate from "the powers that be," are quite sufficient to make the planter cut it a little too fine, and the result is complaints about soft teas, because a liberal allowance of charcoal has not been sanctioned, and the planter must not exceed his estimate. As we have said in former articles, in olden times *pucca batty* lasted about 8 to 10 hours, and in those days there were no complaints of soft teas. With drying machines, times, of course, have somewhat altered, but we would advise planters thoroughly to test the proper duration of *kutcha*, and more especially *pucca batty* in those dryers, as this alone is the only safe test to go by.—*Indigo Planters' Gazette.*

THE CASTOR-OIL TREE.—A member of the Limoges Horticultural Society has made the discovery that the well-known castor-oil plant is fatal to nearly all kinds of insects—a property which adds one more to its already long list of virtues.* Having placed a specimen of the plant in a room infested by flies, the gentleman in question, M. Raffard, found that the flies suddenly disappeared in a most remarkable manner. On seeking to ascertain the cause, he found a large number of flies lying dead in all directions, and more particularly close to the plant, while quantities of flies adhered to the under side of its leaves, which exude an oil that is apparently poisonous to insects. This discovery has suggested the idea of employing a decoction of the leaves as an insecticide. If the plant is equally fatal to aphidæ and the other parasitic insects which are so abundant this season, the castor-oil plant will demand a place in every conservatory, independently of its value as an ornamental shrub; while its cultivation would be advantageous out of doors in all countries whose climate is suited to it. The plant is fairly hardy, and deserves much more attention than it receives, especially in our warmer colonies, where it should find a place for the sake of its invaluable oil. Castor-oil is best known for its medicinal quantities, but it is equally valuable in many industrial arts, and is available for many more purposes than those to which it is usually applied. Its newly-discovered property as an insect destroyer is not the least of its virtues.—*West Australian Inquirer.*

EXTRAORDINARY ANALYSIS OF SUCCIRUBRA BARK.—The renewed bark of a succirubra tree on Braemore estate in the Agras, has given the wonderful outturn of 8·06 sulp. quinine! This comes to us from Mr. J. Buchanan, the manager of the estate. The tree was only 6½ years old, and, curiously enough, the bark was 18 months renewed under mana grass. Most of the former analyses of renewed bark have pointed rather to a decrease of alkaloids after some months or so and certainly seemed to prove that at about 6 months renewal the bark was richest. This wonderful analysis of Braemore bark leads to an entirely different conclusion, and, should other analyses bear out these figures, perhaps we have been harvesting our renewed bark too early. If renewed succirubra can give anything like this outturn, officinalis even in favourable spots, will have to hide its diminished head. We shall await other analyses from Braemore with much interests.—To more thoroughly test the wonderful yield of sulphate of quinine that the renewed bark of a succirubra on Braemore gave, Mr. Buchanan has had an average analysis taken of about 1,000 succirubra trees. The sample tested was carefully taken from each sack, containing the renewed bark from those trees, well mixed together, and therefore is a valuable analysis as showing the average yield of quinine from such a number of trees. Nearly 500 lb. of renewed bark were taken from these trees, 12 months after original shaving, and the result, though of course not so good as the 8 per cent that the single tree gave, still is most marvellously good. The figures are 5·02 sulph. of quinine. The single tree analysed, it will be remembered, was shaved 18 months previously, while the present trees were shaved 12 months before, and possibly, had they been allowed to remain another 6 months, the yield might have been still greater. Mr. Buchanan is about to have another average analysis taken from a number of trees, the renewed bark of which, similarly to the first tree analysed, is now 18 months old. There must be something in Braemore peculiarly suitable to the vigorous growth of succirubra, and to the formation of alkaloids; and should all its succirubras turn out as valuable in quinine as those already analysed, they will indeed be a mine of wealth.—*Ceylon Times.*

KEROSINE AND QUININE.—Hitherto the mode adopted in the extraction of the alkaloids, and in the after separation of the sulphate of quinine has been by the employment of ether and alcohol alternately: both these vehicles are ultimately recovered by distillation for re-use, but for all that there is necessarily a certain amount of wastage in them both. We understand that a more economical process has been adopted by the Milan Manufacturer, by means of kerosine, which is made to do duty for ether, but this method does not as yet appear to be adopted by either English or French manufacturers. The latest suggestion in regard to this process is that the alkaloids should be extracted in the crude state on the spot where the bark is grown, and that they be shipped home in that state to the quinine manufacturer who could then without difficulty separate the ordinary from the more valuable alkaloid. If this could be done with twigs and other inferior and bulky kinds, it would be the means of saving largely in the items of packing and freight.—"Ceylon Times."

CAROB SEED.—During the last two years District Forest Officers in the Bombay Presidency have been engaged in carrying out experiments with carob seed, but the results do not appear to have been very promising. In Sind the Conservator states that all the plants were protected by mats from the frost during the cold season, and adds that when once these plants have established themselves in the soil, they should be able to exist without artificial irrigation of protection; at present they are too small, and it would be premature to express an opinion as to their flourishing in Sind or not. The Superintendent of the Economic Garden at Hyderabad, Sind, also states that though the plant will grow, the slowness of growth will prevent its being of much use except as an ornamental shrub in gardens. The reports from other stations in all parts of the presidency are of a similar nature. At some stations the plants have died, and at others the growth is very slow. In the Government gardens at Poona there are two trees about fifteen years old. The peculiarity of this tree is that it has the sexes on separate individuals. From the female tree in the Poona gardens about 71 lb. of fairly good fruit were obtained in May last year, and the crop would have been heavier if protected from parrots.—*Indian Daily News.*

THE BRINJAL: "AN UNKNOWN PLANT."—The appended letter was addressed by "An Old Indian" to the editor of a well-known London weekly newspaper, and may interest those of our readers who are on the watch to introduce improvements or novelties into the Chinese-European cuisine:—"In your issue of the 30th ultimo I noticed a paragraph *re* 'An Unknown Plant,' and from it have gained some information. I recognised the vegetable the moment I saw it as the 'Brinjal,' which is common all over India and Ceylon, and cooked in a variety of ways. There are two varieties, as we have with the radish, the long and the round. I do not know why the round kind is not imported, they are both equally good. I recollect seeing some of the round kind growing in a garden in Wandsworth some twenty years ago; they were called "egg plant," and were not considered fit for food. My subsequent Indian experience has taught me the contrary. It should be a valuable addition to our list of vegetables for the table. "Knoll kholl" or "kholl rabi" is also a very good table vegetable, if boiled when not too old and tough. It is prized as a vegetable in India. In England it is either unknown or despised as only fit for sheep. It is, on the contrary, an excellent vegetable.—*Penrhyndendraet.*

* In the *T. A.*, vol. I, p. 908, a correspondent called in question this property of the castor-oil plant.—ED.

NEW PRODUCTS IN THE LOWCOUNTRY OF CEYLON.

THE WEATHER—CACAO—TEA—WEEDING—A RETROSPECT—PINEAPPLES—RUBBER.

General Report for March 1883.

The only rain that has fallen this month was a few sprinklings from the outskirts of thunderstorms that spent their force elsewhere. On the 25th, after an elaborate muster of forces threatening a deluge, we were put off with a few hailstones, like pistol balls, and a sharp shower of ten minutes' duration.

Whatever progress *H. V.* may make when the rains come, it has been making none during these dry months. The old spots cannot be obliterated, but no new ones have been formed, for four months. The coffee trees have been growing, but it seems to go mostly to suckers, taking much labour to remove. There have been several small blossoms out during the month, and in this climate there is no difficulty about setting.

The cacao trees are still being teased and held in check by the afternoon winds which still blow daily, but they continue to come into bearing as they get into form and gather strength. The nurseries, what with drought, white-ants, crickets and lizards, are a rather uphill job in these times.

The tea nursery still requires and receives a daily watering, as a good deal of the seed that has germinated is not above ground yet, though other plants are eight inches high. I observe by the advertisements that anything above 60 is considered a fair percentage of plants to seed, and I think I will get 60, if not more, though some of the boxes have given less than 50. My sworn foes, the crickets, have discovered the new venture and make their mark daily, but tea, unlike coffee and cacao, if cut, grows again from the root. I hope to be fully prepared to get the whole planted out during the break storms of the monsoon.

I suspended weeding for a fortnight, because there were no weeds. I am now racing over the field two hands to the acre, and if the daughters do not shoulder mammoties and betake themselves to digging tea holes they must take their otium in the lines till the weeds grow again.

The year 1879, in which I commenced here, was disastrously dry from the 7th of June to the 2nd of November. From that date till November 1882 we had on two occasions twenty days without rain in the centre of what we call the dry season, and we had no light rains during those three years. If a thunderstorm brewed within fifty miles, its course and its central virulence was here, but this season the storms have taken another course. On two successive evenings this month I saw the army of waters muster in the south, and, with the black banner in the centre, march straight upon us. The scouts reached us as fierce gusts of cold wind, the advance-guard in the form of the nimbus approached within three miles, when suddenly the army broke into two detachments: the right marched off to lay the dust in Colombo, and the left to moisten native interests, on the line of country between Hanwella and Kegalla.

Though the progressive growth of all plants has been retarded, the few light rains we have had during the last three months have come on so nearly at the right time, no great harm has been done hitherto, and some of my experimental ventures seem to get on better in dry than rainy weather.

Over ten acres that I cleared this season, I had succeeded in leaving as much shade as I thought necessary for my purpose, but having taken in hand two acres more this month and arranged the undergrowth so as to burn without serious injury to the trees I intended to leave, the fire burned so fiercely, that over more than an acre not one is saved.

Mr. Halliley's answer to my challenge is more in accord with my views than his own. The estate he mentions did not bear the unique series of crops he claims for it (which I would believe if I could) while under weeds, but while under process of being restored to rational cultivation. There seems hardly to be any difference between the cases, repectively adduced by him and by me: both estates were in a bad state from long neglected weeds; both had a large reserve of fertility in the soil; and in both the coffee responded vigorously on the conquest of the enemy that starved it while free scope for its plundering operations were allowed. The same operations which in the fifties restored coffee fields from barrenness to a highly profitable yield may utterly fail in the eighties, because the same conditions do not exist. In the old times weeds were allowed to run their free course, unchecked for years among young coffee, resulting in crops that were hardly worth gathering, while the reserve of fertility in the soil, remained almost intact. Such fields only needed weeding, to bring out in the shape of *pa'am* whatever power the soil possessed. The original fertility of a soil is practically a definite quantity, which is diminished in volume by every particle of matter removed from it, and, unless an equivalent is restored to it in some form, the crops of cultivated land will yearly diminish. A specially favourable season may cause a spurt, but the tendency must always be downwards: quicker or slower, according to the amount of the original fund, but always downwards. For the last twenty years, the general treatment of coffee has been such, as to draw out this fund quickly. From ten to fifteen years ago planters became fully alive to the necessity of giving as well as taking, but before much progress was made in the new direction, *Hemileia vastatrix* came on the clean and the weedy, the sluggish and the enterprizing, the encumbered struggler and the full-handed capitalist alike. A bravely contested battle against this last enemy has been fought, and not won, but it may decline and coffee planting revive on a new system, not Mr. Halliley's.

18th April.—Rain at last, and as usual rather more than we wanted. Herewith a pineapple: it is the second one of this variety I have grown, and the misfortune that has happened to both, has given me a lesson in pinery. If the Kew pine is not supported by a strong stake or otherwise, the weight of the fruit is apt to give the plant a list, and as soon as the plant leaves the perpendicular the fruit stem snaps across, like a pipe stem. This one is hardly mature, and so far short of the dimensions I have heard of; yet it is a fruit of highly respectable appearance. I have not wished to say anything about Ceara Rubber, till I see what comes of the present death-like appearance of the trees I believe something of the same kind has happened elsewhere, but for the present all that have borne seed are leafless as well as some that have borne none. Everything is looking fresh and flourishing after the rain.

Kuskus Roots.—Mr. A. C. Sumps writes:—"With reference to Mr. A. P. Abraham's desired information on kuskus roots and to your editorial query therein referred to, in your issue of the 20th inst., I have the pleasure to state that I use kuskus for tats, for the hangings of punkahs and for fans. The kuskus tats hanging all round the Grand Oriental Hotel verandahs are those supplied by me."

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From LEWIS & PEAT'S London Price Current, March 29th, 1883.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White	Slightly softish to good hard bright	£6
Yellow	Do. drossy & dark ditto	£5 a £6
CINCHONA BARK—Crown	Medium to fine Quill	2s a 3s
	Branch	1s 6d a 2s
,, Red	Medium to good Quill	1s 9d a 3s
	Branch	1s a 1s 6d
,, Twig		1½d a 6d
CARDAMOMS, Malabar	Clipped, bold, bright, fine	6s 6d a 7s
	Middling, stalky & lean	3s 6d a 5s
Alleppee	Fair to fine plump clipped	4s a 5s
Madras	Long, lean, to fair	2s 6d a 4s 6d
Mangalore	Good & fine, washed, bgt.	7s a 8s
Ceylon	Middling to good	2s 6d a 3s 6d
CINNAMON 1sts	Ord. to fine pale quill	1s a 2s 5d
2nds	,, ,, ,, ,,	10d a 2s 1d

THE CEYLON COFFEE-PLANTING INDUSTRY:

CEYLON AS AN 'INCUBATOR" FOR ABSENTEE CAPITALISTS.

Crop prospects are not cheering. Though the coffee crop of 1883-84 will assuredly exceed that of the season just past by probably a large amount, it will fall very far short of what might reasonably have been expected from the appearance of the "bearing wood" on which our hopes in December last were founded. Owing probably to the very light crop of last year, the wood for this year's coffee crop matured very early. Even so soon as the latter days of November the eyes were swelled with coming spike, and they continued to put forth bud throughout December and January, but the persistent rains which then prevailed, prevented the spike from coming forward into blossom. When, at last, fine, hot, sunny weather came, the eyes on the best of the mature wood were already nearly exhausted, and the blossoms which followed were mainly formed on the younger wood since forced out by the rain of the early blossoming season. We shall, no doubt, have a crop to pay expenses on all, or nearly all, estates that have had fair cultivation, but not such a crop as was wanted to lift the clouds that hang over our enterprize. Long as these clouds of debt and depression have been lowering over us, they seem yet destined to darken our prospects.

True, we are still sharing a common lot. Agriculture elsewhere, especially in our own country, suffers equally from repeated and successive disappointments. After eight years of deficient harvests in succession, a ninth is now almost assured to our fellow-agriculturists in Britain. Still, though their misfortunes may be as great as ours, they are not so ruinously felt. In times like these, the fatal peculiarity of our local enterprize manifests itself in its fullest force. The "accumulated profits," made during the time of prosperity, which at home form a reserve fund of local wealth to enable the sufferer from present adversity to benefit by past earnings, are utterly wanting in Ceylon. We have no reserve fund of past profits to fall back upon, no class of wealthy Europeans enriched by former times of prosperity living amongst us and circulating the liquidated products of former industry.

Ceylon, in fact, is a sort of *incubator*, to which capitalists send their eggs to be hatched, whence they receive from time to time an abundant brood, and leave us but the shells for our local portion. Money has been sent here to fell our forests and plant them with coffee, and it has been returned in the shape of copious harvests to the home capitalists, leaving us in some cases, the bare hillsides from whence those rich harvests were drawn. Had the profits from our abundant coffee crops in the past been located here, and invested in the country and its soil, what a fund of local wealth would now exist, what new industries might have been created, what manufactures might now have been flourishing, what numbers of wealthy citizens of our own race might have been living in affluence, and what resources should we not have possessed to help us over the time of our adversity and depression!

The total amount of coffee raised on the plantations of Ceylon since 1849 is about *Cwt.* 18,100,000
and there were produced previously (excluding native coffee in both cases) about ... 1,000,000

At the least, making a grand total of coffee of as the produce of imported capital. Including interest, and all items of local cost, we may safely say that this coffee has been produced for 25 rupees per cwt. and has realized, at the least, R35 net, on an average; and it has therefore thus earned a net profit of R191,000,000
The coffee so produced has been yielded by plantations aggregating not more than 320,000 acres after including a due allowance for lands abandoned; and the average cost of the estates, including the purchase of the land, has certainly not exceeded R300 per acre, involving a total capital of R96,000,000
There has therefore been a sum of at least R95,000,000 of liquidated *profit* returned to the capitalist, besides the refund of his *principal*, and there remains still the existing plant of say 250,000 acres of land under cultivation by means of the said capital worth surely R150 per acre R37,500,000
thus showing a total profit at the very least of R132,500,000

19,100,000

In short, we have dispatched a brood of 95 millions, and have 37½ millions still in the shell!

Hence comes it that, though we possess many of the outward and visible signs of national wealth, such as abundant revenues, great public works, railways, roads, harbours, tanks and irrigation works, public buildings (not omitting the Asylum!), yet there is not a wealthy European in the island. Though we have heaped up riches elsewhere, we have made no local piles and are absolutely without any reserve of liquidated accumulations to meet the era of short crops and of financial disaster which began in 1879.

It must be remembered that in the above remarks on "Ceylon as an incubator for absentee capitalists," we were dealing with the enterprize from the colonists' point of view, and only took into account the "plantation" coffee exported. The profits on the six or seven millions of cwt. of "native" coffee exported have all come to the Ceylonese people concerned, and moreover a large proportion of the "R300 per acre" and "R25 per cwt." allowed for expenditure on plantations and crop has directly gone into the hands of the people and so far benefited the island. But here again, a considerable amount of what has been paid to Tamil coolies—over thirty millions' pounds sterling in about 40 years—apart from the rice, curry-stuffs and cotton cloth purchased by them in Ceylon has gone in the shape of their profits to benefit Southern India. Here the Imperial Government give us no credit as a Colony, nor has it been realized in England that, during the Madras famine of 1877-78, well nigh 200,000 fugitives found means of subsistence in Ceylon, over and above the usual labour supply of the planters. Indeed, in this way, Ceylon—mainly through its colonists—contributed about as much to the aid of India as the total of the "Mansion House Famine Fund" about which so much was heard at the time. But to turn more particularly to further disadvantages we labour under, it will be found that it is not only the profits of our European agriculture of which the country fails to reap the benefit. Her highest and best-paid officers carry away, on

their departure from the country, a large proportion of what they did not remit "home" during the brief tenure of their office. The whole Civil Service, as a body, also remit a large proportion of the pay they draw from the island's revenues to maintain and educate their families *at home*. And when, at length, their terms of service have been completed, their pensions, swelled, it may be, by rewards for services elsewhere, are drawn from the island's resources and permanently alienated from its wealth. Even our commerce contributes its profits to the mother-country and leaves "the empty shells" in the place whence the substantial brood has been driven.

ADULTERATING INDIAN TEA WITH MATÉ! THE USE OF MATÉ IN S. AMERICA.

The extraordinary proposal of the *Indian Tea Gazette* to blend maté with Indian tea is thus noticed by Mr. P. D. Millie's brother in South America :—

"The *North China Herald*'s idea about the virtues and defects of maté are jumbled up with something which can only have reference to the Bolivian *coca*, about which much crude nonsense has been written, and which in its turn has been jumbled up with cacao or cocoa or vaguely inferred to have some connection with coconuts, or to be some preparation therefrom derived!

"I frequently use Paraguay tea or *maté*, and can assure any one wishing to know the truth that it is not tea at all, and is for a certain reason utterly unfit to be used to 'blend with Indian teas.' Maté parts with its flavour and colouring matter almost instantaneously by pouring boiling water over the leaves, and this may be repeated several times without exhausting them. Tea, on the contrary, parts *slowly* with its theine and colouring; if mixed with the leaves of the maté ilex, its flavour would be utterly overpowered by that of the latter.

"Maté does *not* produce any 'excitement of a very unpleasant kind to Europeans.' On the contrary, I know Europeans who cannot take tea who resort to maté, because it does not produce the excitement to the nervous system caused by tea, including insomnia. Judging from its effects on myself, I consider it to be one of the most harmless of warm infusions, and have always liked it. The South American peoples who use it certainly do not suffer from its exciting properties, although many of those who imbibe maté in great quantities object to a cup of tea because it affects their nerves.

"Maté is an excellent *substitute* for tea: as a *blend* it never can be used. We use it in South America either by pouring boiling water over the pulverized leaves and twigs, adding sugar to suit the palate, and then sucking it through a silver tube, or by infusing the entire leaf in a teapot or jug, and pouring it out like tea. The latter way of preparation is not very common yet, but will, I think, soon become more general. Undoubtedly it is a good morning or evening beverage for nervous persons who cannot take tea.

"This is the plain truth about *maté*. It will never supplant tea in Europe or elsewhere, and will never be employed (at least successfully) to adulterate the latter. It is a beverage *sui generis*, and, although I enjoy a *maté* now and then, I have no inclination to abandon the use of tea. Rich and poor among the natives of the Spanish American Republics use it: but for all that tea and coffee are yearly being consumed to a greater extent by all classes whilst the consumption of mate remains about stationary.

"Coquimbo, Chile. T. J. W. MILLIE."

LABOUR IN FIJI.

We have already noticed the effect of Sir Arthur Gordon's regulations by which most of the natives of Fiji are prevented from labouring for European employers on estates. Then, it appears, that, while in Queensland the exceptional mortality amongst the South Sea Islanders (kanakas) is attributed largely to a change of diet, including too large a proportion of meat, a similar exceptional mortality amongst the same class on Fiji plantations is traced to a diet too exclusively vegetable. The present editor of the *Fiji Times* admits that the main food consists of wild roots gathered in the forests called "tivolis" and sweet potatoes often unripe. Yams ought to be cultivated and supplied more largely, with meat or fish. We cannot forget the terrible mortality amongst Tamils in Ceylon in early times, but the kanakas seem specially unable to bear regular work and exposure on the weather. The following is an extract from a report by Dr. MacGregor :—"The frightful mortality among the Polynesian laborers has been variously ascribed by employers to acclimatization and the overflow of the river some five or six months ago. As the Polynesian can hardly be said to be submitted to a change of climate by removal to Fiji, where also he is understood to be fed on precisely the same kind of food he has always been accustomed to, the cause or causes of mortality cannot be ascribed to acclimatization. Nor can it be imputed to the overflow of the river, seeing that the health of the Indians has not been affected by it. It is, however, notorious that the mortality amongst recently introduced Polynesians is very much greater than among old residents. This is not in my opinion owing to the climate, but is due to changed conditions of living. Polynesian youths and boys that have hitherto led a lazy and indolent life are brought from their own country, set to do continuous and hard work, fed on food of inferior quality and exposed to all kinds of weather. There can be no doubt the class of Polynesian now introduced is greatly inferior in physique to that formerly brought to this Colony; they are therefore less able to bear the transition from their previous mode of life and they have a greater liability to sickness when exposed to contagion—such as that of dysentery—and less recuperative power; few of them can undergo without injury the fatigue of a fair day's work for an average healthy man, and they have less power of resistance to the chilling and lowering effects of bad weather. The suggestions made to the different managers in my letters have reference specially to houses, food, water, sleeping accommodation, the treatment of the sick, exposure, and work." After dealing with the sanitary arrangements of houses and condemning unripe sweet potatoes. Dr. MacGregor proceeds :—"I observed on two or three estates that the Polynesians at the time of my visit were eating rice, which they said they relished. At * * * * a considerable number are now using flour made into cakes of the kind prepared by the Indians. The use of both these articles of diet should be encouraged as the supply of yams and taro will constantly and rapidly become more and more disproportinate to the demand, on account, on the one hand of the employment of the natives in the cultivation of sugarcane, and by reason on the other hand of the ever-increasing number of laborers employed on the estates. I am strongly inclined to think that the planters will find it cheaper to use rice and flour than to plant yams and taro on their own estates. The use of manioc or kassava deserves a trial as an article of diet. It can be grown cheaper, and as a crop is much less precarious than yams. It is largely used by planters in Seychelles, and is there a healthy and nutritious diet. In all other tropical countries with which I am familiar it is considered necessary that the coloured laborers should receive a certain

allowance of animal food. This is most frequently given in the form of salt fish. I believe this addition to their food is as necessary in Fiji as elsewhere, and I would therefore raise this point for the consideration of the Governor." Mosquito nets for estate labourers sounds to us absurd, but in Fiji they seem an absolute necessity, for Dr. MacGregor writes :—"In preserving the health of the labourers it is of much importance that they be put in a position to procure, at night, sound sleep and rest to the body. This is hardly attainable on any single estate visited by me. In most cases the mosquito nets were highly objectionable, incapable of excluding mosquitos in the majority of cases; but, in one instance, made of thick calico, and therefore too hot and close. In almost every case, if not in all, the labourer sleeps on a hard plank or on *ratas* (shelves) constructed of bamboo, covered usually with a single mat. It is difficult to believe that a tired man can rest his body sleeping on a hard plank, and I would therefore insist on the use of a certain quantity of some soft material below the mat. Mosquito nets, I hold, should be of a white colour, to make sure of their being kept clean : the meshes should be large enough to permit the circulation of air, but not so large as to allow the entrance of mosquitoes. Care is also needed to prevent too many men from occupying one mosquito net." The comparison instituted between Polynesians and Indian coolies shows why planters accustomed to docile kanakas find coolies too independent :—"Although a matter that is difficult to prove by actual demonstration there is much reason to believe that exposure to cold and wet has much to do with the very frequent occurrence of fatal dysentery among the Polynesians. The Polynesian is placed at a great disadvantage compared with the Indian. The Polynesian is much more passive, greatly more ignorant, and far less able to protect himself than the cunning, exacting complaining Indian : and yet the law protects the latter to a very much greater degree than it does the former. The Indian nearly always works by the task—that is by piece work. If he feels in any way indisposed, or if the weather is bad, he need not work; and thus he avoids exposure, and can rest if ailing. If he does more than an average day's work in fine weather, he is paid accordingly. The Indian feeds himself and can therefore select his own food : and he possesses naturally, a certain amount of talent in cooking, and in making himself comfortable. His position is therefore greatly superior to that of the Polynesian, who little understands how to make himself comfortable, whose services at all times and in any weather are at the call of his employer. He eats what is given to him, which is, I fear, often of bad quality, and cooked in the roughest possible manner; he lives without complaint in any house or hovel put at his disposal by his employer, and accepts whatever accommodation is supplied to him. Unless his employer gives him a specified task the Polynesian has but little idea of hours or of a fair day's work. When sick his passiveness and docility become helplessness. Surely if this comparison of the two races is a fair one, and as it is based on my own observations, I believe it is not misleading, the law should provide greater protection for the Polynesian than for the Indian. The legal safeguards furnished the Indian are not greater than are required; in the case of the Polynesian they are less than experience demands."

REPORT FOR 1882 OF THE PUBLIC GARDENS AND PLANTATIONS IN JAMAICA.

We have already noticed that portion of Mr. Morris's elaborate Report which dealt with the production and export of table fruits to the United States. Reverting to the document we find it stated that, in consequence of the failure of the May rains or "seasons," after a series of dry months with parching winds, all agricultural operations suffered from drought. Young coffee and cinchona plants suffered very severely, and precautionary measures had to be taken with reference to the water supply of Kingston. Old planters in Jamaica, like old planters in Ceylon, believe that the seasons are more irregular and precarious than in former days, and there is an evident inclination to lay the blame on forest denudation. But the clearing away of forest can scarcely have produced, simultaneously, unseasonable drought in Jamaica and unseasonable rains in Ceylon. Trees may have important local effects, but the seasons are surely influenced by great cosmic forces beyond the control of man. No doubt lands entirely bared of timber are specially liable to injury from floods. Mr. Morris has, therefore, only performed his duty in recommending for consideration the preservation of forest on mountain tops and ridges as well as in the neighbourhood of springs and on the banks of rivers. Jamaica, like the whole of the West Indies, is subjected to much more violent meteorological phenomena than are ever experienced in Ceylon. No wonder, if the export of produce from Jamaica was diminished in 1881-82, when we learn that severe floods in 1879 were followed by an unprecedented drought in 1880, to which a hurricane was added, drought continuing, in 1881 ! Nevertheless, Mr. Morris writes :—

At the close of the year 1881, in spite of the drought of that year there were many hopeful signs of improvement. The sugar crop, grown in localities not seriously affected by the decreased rainfall, was the largest for many years; the exports being sugar, 38,392 hhds. of the value of £614,283, and rum 22,742 phns. of the value of £295,645; which is an increase on the exported value of these two articles, as compared with 1880, to the extent of £398,621. The coffee crop as a whole was above the average, but on account of the low prices ruling for this article, many of the settlers growing lowland coffee suffered severely. For the best qualities of Blue Mountain coffee, grown and cured by skilled labour, the prices appeared to have been little changed.

Many suggestions have been made to deal with the evil but deep digging and treating with caustic lime, while the insect is in the larval state, appears to be the only effective means of destroying it. Careful rolling of the surface with a heavy roller when the ground is soft might also be tried: as well as assiduously destroying the adult insects whenever practicable.

There are no figures for the coffee crop, but, allowing for local consumption of sugar and rum, the value of products of the sugarcane exceeded one million sterling, notwithstanding the prevalence in some districts of an aphis blight in the canes, as also a destructive caterpillar : but the latter for only a few weeks. Much mischief has been done to pasturage by the mole cricket (*Grillus campestris*) so wellknown on lowcountry estates in Ceylon, where the insect flies at higher game than grass roots, to wit cacao and Liberian coffee seedlings. Mr. Morris writes :—

While on the subject of insect pests in this island, I would desire to draw attention to the fact that I have noticed that such pests are most prevalent in the neighbourhood of villages and in localities where bird life is rare or entirely absent. Owing to the indiscriminate slaughter of small birds in this island, where every one with means sufficient to purchase a gun can shoot all the year round, bird life (especially humming birds, redstarts and others of an insectivorous character and with bright plumage) is becoming more and more rare.

It would be very desirable to restrict, if not entirely abolish, the shooting of all birds in this island during certain seasons; but I would earnestly recommend that, at least, protection be given to the large class of insectivorous birds which is now practically becoming exterminated.

There can be little doubt that we suffer more in Ceylon from "grub" than we might, if insectivorous birds were more plentiful. But birds have an unhappy faculty of changing their habits; and there are no greater enemies of wheat growers in Australia than parrots, while the imported sparrows are equally destructive to cherries. Coming to "exchange of plants and seeds," we find it stated :—

Among the special contributions received from Kew were the following :—seed of Cinchona Ledgeriana; cinchona morada veluta (Cinchona calisaya, Boliviana); cuprea bark (Remija pedunculata?); the Mangaba (Hancornia speciosa) which, besides being one of the sources of India-rubber in Brazil, bears a most delicious fruit.

We suppose Dr. Trimen's forthcoming Report will tell us that seeds of the Cuprea bark trees (which flourish at much lower levels than the true cinchonas) have been received in Ceylon as well as of the tree which, besides producing rubber gum, yields a delicious fruit. That tree ought certainly to be an acquisition. Considerable additions had been made to the Botanical Library, amongst which we notice "Freaks of Plant Life" by Cooke, and "Vegetable Technology" by Jackson. At the cinchona plantations, elevation 5,000 feet, the mean temperature of the air and of the earth 6 feet below the surface was 63°. As Jamaica is 10° further from the equator than either Java or Ceylon, it is curious that the mean temperature at 5,000 feet should not be lower in the West Indian Island than in those within 7° of the equator in the British and Netherlands East Indies. If there is no mistake, we should be glad to learn what the influences are which give Jamaica a mountain climate in 17° North as warm as that, which prevails at precisely similar altitudes in Ceylon 7° north and Java 7° south of the equator. In British Sikkim at 10° farther north than Jamaica we know that 3,600 feet altitude is equivalent to 5,000 in Ceylon, each giving a mean temperature of 63°. The difference for 20° latitude is 1,400 feet altitude. As British Sikkim is close below the everlasting snows of the Himalayas, the cold of winter may have some effect in reducing the mean temperature. Instead of 700 feet for 10° in the case of Jamaica, therefore, let us take 500. Even then, by analogy the mean temperature of 63° should in the West India Island distinguish an elevation of 4,500 feet, and at 5,000 feet the mean should be, not 63° as shewn, but about 60°. Do the contiguity to a great continent in the case of Ceylon and the vast mass of Java and Snmatra (practically one island) account for the difference; or is the heat of Jamaica raised by the waters of "the Gulf Stream" or by warm air currents? It is, at any rate, curious that Jamaica at 17° from the equator should have the same mean temperature at 5,000 feet, which is shown at the same elevation in Java and Ceylon at 7° from the equator. Against a mean of 63° at 5,000 feet in Jamaica, we have a mean maximum of 68·9 and a mean minimum of 58·4. The highest range was 72·8 in June and the lowest 54·4 in February. The mean of the dew point for the year was 57·9. The rainfall for 1881-82 (a year of drought) was 73·77. The rainiest month was October 1881 with 34·52 inches, November coming next with 8·02, while June gave only 0·76. From a table of rainfall for ten years we gather that by far the rainiest tion of thepor year extends from August to December, the average being :—

August	11·44 inches	Nov.	9·57 inches
Sept.	12·76 ,,	Dec.	12·97 ,,
October	20·74 ,,		

May in the other months of the year makes the best shew, thus :—

January	9·90 inches	May	11·74 inches
February	3·19 ,,	June	5·78 ,,
March	7·39 ,,	July	4·72 ,,
April	7·05 ,,		

The rainfall (average for the year 119·10 inches) is thus very fairly distributed. The averages were reduced by 68 inches only in 1881, the lowest of the series, and 73·77 in 1882, the next lowest. Except October every month of 1881-82 was below the average of 9·93 inches; the monthly average for last year being 6·14 inches. The highest rainfall in ten years, 156·82 inches, occurred in 1877; the lowest, as we have shown, was 68 inches in 1881. The highest fall in any month in the ten years was 43·74 in December 1878, and the lowest 0·76 in June 1882. The climate is certainly all that could be desiderated for cinchona culture, but the great factor in favour of Jamaica, as well as Java, must be the soil, for in Mr. Morris's reports we see nothing said about the dying-off from root and stem canker, which has so largely qualified the profit of the enterprize in Ceylon. All we can see about disease is that four plants of the hard Carthagena kind were exhibiting the most luxuriant growth at 6,100 feet, but that at lower elevations they did not do so well. "At elevations of even 5,000 feet they are attacked by *red spider* and *thrip* and make very slow progress." Red spider and thrip are, therefore, present, and, if canker is as entirely absent as Mr. Morris's silence on the subject would lead us to infer, we should like to know what, in Mr. Morris's opinion, is the reason why. We have little doubt he would answer "*soil*," adding, perhaps, "shelter," for it does not seem that the hurricanes have done much damage to the fever trees.

The first of the numerous gardens under his charge reported on by Mr. Morris are the "Castleton Gardens," 580 feet above the sea, with a mean temperature of 78° and a rainfall of 92 inches. A number of improvements was effected, and we are told that

These banks instead of being turfed with sods in the usual expensive manner were replanted, at a comparatively small cost, with small pieces of Bahama, Cynodon Dactylon, and other stock-spreading grasses, and after the interval of only a few months they now present a beautiful green sward.

Large numbers of seeds and plants were distributed from these Gardens : amongst the rest 6 barrels of mahogany seed to the Royal Gardens at Kew for transmission to India and 10 lb. to the Nizam's Conservator of Forests. The rainfall at this altitude had varied as follows :—

1879-80	...104·00 inches
1880-81	... 76·80 ,,
1881-82	... 90·56 ,,

The first year noted was distinguished for floods, and then came the reaction to 76·80 inches instead of the average of 92.

We now come to the "Cinchona Plantation," 5,000 eet altitude, 63° mean temperature, and 119 inches average rainfall. We quote as follows :—

In my report for the year ending 30th September, 1880, I mentioned that the object of the Government in maintaining these plantations was not on account of the pecuniary returns likely to be yielded by them, but for the purpose of showing that cinchona barks of good quality could be successfully grown in Jamaica; and also that cinchona planting, as an enterprise in private hands, possessed all the elements of a sound and remunerative industry.

The sales of Jamaica-grown cinchona bark during the last three years, having, I believe, fully proved both these points, the Government Plantations may now naturally devote chief attention to the successful introduction and cultivation on a small scale of all the newer and richer kinds of cinchonas for the purpose of successfully estab-

lishing them in the island; and, also, to such necessary experimental and scientific work relating to the industry which, for lack of means or of scientific knowledge, cannot be conveniently undertaken by private enterprise.

As already mentioned much remains to be done in this repect; and as the plantations as a whole do not contain more than about 180 acres, this will not allow on the average more than about five acres for each of the twenty-five or thirty species, varieties and forms of cinchona barks now the subject of careful experiment and investigation on these plantations.

In order to test the commercial value of Jamaica-grown bark, no better plan could be followed than to send it in lots to the open market and place it in competition with barks from other countries. That it has so satisfactorily stood this test and brought in a large return on the outlay, and, moreover, that the results of the sales have induced cinchona planting to be undertaken in the island by private enterprise with energy and success, are matters for which the Government no less than the general public are to be congratulated.

Three years ago the kinds of cinchona barks under cultivation here were only three:—viz., cinchona succirubra, cinchona officinalis, and the so-called cinchona calisaya, now proved to be indentical with cinchona hybrid or *robusta* of Ceylon and India.

Since that time, numerous kinds have been introduced which are now the subject of careful experiment to determine the most favourable circumstances of soil, elevation, rainfall and aspect suitable for their successful cultivation: the best methods for barvesting the bark and inducing the largest formation of alkaloids, as well as determining the simplest and most economical methods for their general treatment and management.

Among the kinds of bark now under experimental cultivation at the Government Plantations are:—

Red Barks.—Cinchona succirubra; cinchona succirubra, var. sub. pubescens.

Crown Barks.—Cinchona officinalis; cinchona officinalis, var. uritusinga; cinchona officinalis, var. Bonplandiana; cinchona officinalis, var. crispa; cinchona officinalis, magnifolia; cinchona officinalis, pubescens.

Hybrid Bark.—Cinchona hybrid or robusta.

Ledgeriana Bark.—Cinchona ledgeriana.

Yellow barks.—Cinchona calisaya; cinchona calisaya vera; cinchona calisaya, var. Josephiana; cinchona calisaya, var. Javanica; cinchona calisaya, verde; cinchona calisaya, morada form.

Grey Barks.—Cinchona peruviana; cinchona nitida; cinchona micrantha.

Carthagena Bark.—Cinchona lancifolia.

Cuprea Bark.—Remija pedunculata?

There is, I fear, some confusion respecting the classification of more than one of the cinchonas now under cultivation in the East and West Indies. Many names, especially of the varieties or forms of the large class of Crown barks, require to be carefully revised, and, on that account, the above enumeration is only intended to indicate the names under which certain kinds have been received here.

During the past year chief attention has been given to the successful introduction of cinchona ledgeriana and its establishment as a cultivated plant in Jamaica. In addition to the plants established on the Government Plantations several thousands have been distributed amongst private planters, and each lot of these will doubtless form a *nucleus* from whence seeds and cuttings may hereafter be obtained and thus prove most valuable acquisitions to private plantations.

In connection with the general working of the Cinchona Plantation, I would mention that Mr. Hart, who was lately appointed superintendent in succession to Mr. Nock, has devoted himself with commendable energy to the duties entrusted to his care, and I have confidence that he will prove a capable and valuable officer.

It will be seen that no fewer than thirty-five species, varieties and forms of cinchona were the subjects of investigation in the area of 180 acres, against only the three leading species when Mr. Morris took charge, what was called calisaya, however, turning out to be identical with the hybrid or robusta of Ceylon and India. It will be noticed that Mr. Morris classes *pubescens* not as a hybrid, but as a variety of succirubra. His list includes also a pubescent officinalis. Amongst the yellow barks we find calisaya verde and the morada form. The classification requires revision, however, and we have little doubt that Mr. Morris's list of thirty-five will be considerably reduced.

Then follow details regarding nurseries, &c., and we find that from the plantation were distributed 372 ounces of seed, 77,961 plants, and 362,250 seedlings. The plants included 4,108 Ledgerianas, and of the valuable and hardy hybrids the distribution was 52¾ ounces seed, 750 plants and 91,800 seedlings. We quote again:—

Seed of cinchona ledgeriana continues to be received in small quantities both from Java and India and a proportionate number of seedlings are raised to supply the demands of private planters. Seed of an apparently new kind of Cinchona belong to the Calisaya or Yellow bark—Calisaya verde (*Cinchona Calisaya oblongifolia*) introduced by Mr. Christy, has also been received and the plants, though few in number, are doing well. A small quantity of seed of Calisaya morada veluta (*Cinchona Boliviana*) was received from Kew, which I trust will also be successfully raised.*

A few plants of the Cuprea Bark, *Remija pedunculata*? raised from seed received from Bogota, are also being tried in order to test the value of this bark under cultivation.

After details on conifers and other ornamental and useful trees grown on the plantation, we are told that:—

Numerous cuttings from the three Ledgeriana trees received from Kew in 1880, have been rooted in the propagating houses and after being hardened, they were planted in a well-prepared and sheltered spot near the nurseries. They are 50 in number and are growing well.

---

* Referring to these barks the following note has been made upon them by Mr. E. M. Holmes, F. L. S., Curator of the Museum of the Pharmaceutical Society of Great Britain:—

"With respect to the leaves and fruit, so far as I can judge, the '*Calisaya morada veluta*,' is the *Cinchona Calisaya Boliviana* subvar. *pubescens* of Weddel's Notes (Transl. p. 44), and the *Calisaya verde* is, so far as I can ascertain, Weddel's *Cinchona Calisaya oblongifolia*, and the tree concerning which Markham ('Travels in India and Peru,' p. 270) gives the following account:—'I have been assured by Gironda and Martinez that there are three sorts of Calisaya; *Calisaya fina* (*C. Calisaya a vera*, Wedd.), the *Calisaya morada* (*C. Boliviana*, Wedd.), and the *Calisaya verde*. They also told me that the last-named tree was a very large one, with leaves whole devoid of any red colour on the nerves, and habitually growing very far down the valleys and even in the plains. A tree of this variety supplies 600 to 700 lb. weight of bark, whereas the *Calisaya fina* yields only 300 to 400. Gironda declares that in the province of Muñecas, Bolivia, he saw one that furnished 1,000lb. of tabla, that is to say, of the bark, of the trunk, and lower branches.'

"These remarks confirm the statement made in the copy of the letter forwarded with the barks, viz., that it pays better to cultivate the *Calisaya verde* than the *Calisaya fina*, or, in other words, that although the *Calisaya verde* yields only 6½ to 9 per cent. of pure sulphate of quinine (while the very best Ledgeriana yields 13 per cent., and other specimens not more than 6 per cent.) yet as the *Calisaya verde* yields twice the amount of bark that the *fina* or Ledgeriana does, this equivalent to from 13 to 18 per cent. of quinine in the *Calisaya verde*; moreover, from the fact that the *Calisaya verde* is a more vigorous tree than the delicate Ledgeriana, and will grow at a lower elevation, it is obvious that it can be cultivated to a much greater extent and may be extremely valuable for grafting the Ledgeriana upon, more especially since the attempt to graft the Ledgeriana upon *C. succirubra* has proved unsuccessful.

"I am not aware that the *Calisaya verde* (*Cinchona Calisaya oblongifolia*) has yet been introduced into India, and I think you are to be congratulated on having succeeded in obtaining seeds of so valuable a Calisaya."

Some scions] from the same trees were grafted, about the middle of August, on roots from strong growing healthy trees of "Hybrid" and they have now united and have commenced making healthy growth.

UPPER BUZZA PLANTATION.—Te operations on this plantation have consisted chiefly of the routine weeding, cleaning and supplying vacancies. The trees of all kinds have made satisfactory progress, some of the "Hybrid" plants being over 10 feet in height at a little over 3 years old.

Some of C. Officinalis, now about 2 years and 9 months planted, are over 7 feet in height and being closely placed and often two at one stake, they will soon require thinning.

It is estimated that bark could be taken from this plantation next year (that is, in the fourth year after planting) to the value of at least £15 per acre, net. The number of plants supplied to this plantation (in the last planted portion) was about 6,000 C. Officinalis, and 580 C. Hybrid.

BELLE VUE PLANTATION.—The principal field operations of the year have been for the most part, confined to this plantation, and have consisted in the clearing and replanting of the too widely-planted portions described in former reports.

The portion treated last year and planted with C. Officinalis var. uritusinga has, notwithstanding the severe drought, grown well—except in some few denuded ridges where ferrugineous clay crops up through the upper or surface soil; the general growth of the entire field is on the whole very satisfactory. Adjoining this portion, a field of about 5 acres has been cleared and planted with C. Officinalis of the same variety (Colorado de Loxa of Spanish commerce) as that growing at the Newbaven Gap and Monkey Hill plantations. The land was first thoroughly cleaned and then dug into the form of ordinary yam-hills 3½ feet by 3½ feet apart. These hills were allowed to settle and become soaked by a few showers of rain previous to planting. Three large drains dividing the slope (which is rather steep) into four portions have been made for the purpose of counteracting the effect of heavy rains and preventing wash.

On this plantation, also, a site has been selected and partially prepared for plants of the glabrous variety of C. Pubescens (Magnifolia) raised from seed received from the Indian Plantations.

WHITE'S PIECE.—The growth of the Hybrid plants on these fields continues to be very satisfactory, and the plantation generally is in good order. It will be remembered that this is the second planting of Cinchona on land from which a large crop had been previously harvested, and the general health of the plants leads me to hope that the second crop will be fully equal to the first.

NEWHAVEN GAP AND MONKEY HILL PLANTATIONS.—These fields, established mostly with C. Officinalis, were cropped last year and a total of 60,194 pounds of wet bark, yielding 21,512 pounds of dry bark, was successfully shipped therefrom. The results of these sales will be discussed later. The fields are now in good order and with the coppiced stools sending out abundant shoots, some of which are 14 inches high. It has been noticed that with C. Officinalis on these fields the stools have in no instance failed to throw out shoots, and they have maintained their health and vigour after being coppiced two or three times.

Four plants of the hard Carthagena Bark received from the Government of India have been established near Monkey Hill hut (6,100 feet) and at this elevation they are exhibiting most luxuriant growth.

Plants of the same kind are also established at lower elevations, for experimental purposes; but, judging from their relative rate of growth and their habit, it is evident that this kind is adapted only for the highest elevations in the island.

At elevations of even 5,000 feet they are attacked by "red spider" and "thrip" and make very slow progress.

LATIMER PLANTATION.—On this plantation a small sheltered spot has been selected for experimental trial of Cinchona Ledgeriana at 5,500 feet. As in the other cases, where this kind is planted, it is hoped to keep the plants free from hybridization and so ensure pure seed.

It will be seen that Mr. Morris had been successful in grafting Ledger scions on to hybrid stocks, and that the growth of hybrids and officinalis was good. It is interesting to learn that a second planting of cinchona on the same land was likely to be a success. *C. officinalis* trees had coppiced well two or three times, still retaining their vigour. We shall be curious to know how Ledgerianas answer in Jamaica at 5,500 feet. The fact that the site is sheltered is of much importance.

We now come to the

RESULTS OF BARK SALES, 1881-82.—One shipment of bark was made from the plantations during the past year, which for the most part was the result of "thinnings" and "prunings" of New Haven Gap and Monkey Hill plantations, rendered necessary by the too abundant growth of established trees and self sown seedlings The bark thus harvested was composed of "twig and broken bark" but the results of the sales were of a very satisfactory character. The net amount realized was two thousand, four hundred and nineteen pounds five shillings and seven pence, being four hundred and nineteen pounds five shillings and seven pence beyond the estimated value of the consignment.

The results of the sales may be briefly summarized as follows:—

Kind.	Gross Weight Shipped.	Deductions for Sample Dust, &c.	Net weight Sold,	Av. price p. lb. on all Qlts.	Total Amount Realized.
Cinchona Bark.	lb.	lb.	lb.	s. d.	£ s. d.
Cinchona Officinalis.					
Root bark	2,342	275½	2,066¾	4 9½	495 4 5
Stem bark	10,448	1,224¾	9,223¼	3 1½	1,484 2 7
Twig bark	7,320	1,129½	6,190½	1 4¾	436 18 9
Mixed bark	92	10	82	3 4½	13 17 2
Garblings, dust, &c.	1,310	140½	1,169½	1 10½	108 19 9
Total ...	21,512	2,780	18,732	...	2,539 2 8

As compared with consignments from other countries, the prices obtained for Jamaica-grown bark were most satisfactory and encouraging.

It will be noticed that the highest prices, viz., 8s and 4s 11d per pound, were obtained by no other C. Officinalis bark in the market, while they were approached only by one sample of Calisaya bark, usually considered more valuable than Officinalis bark, which sold for 5s 3d per pound. The high prices referred to are shown in a detailed table for which we cannot make room, but we may say that 248 lb. "fine root" bark of *C. officinalis* sold at per 8s lb., 1,144½ "fair root" at 4s 5d, and 674¼ "fair root" at 4s 3d. The root bark sold highest of all, a result which, for some reason we do not understand, does not now hold good in the case of Ceylon cinchona. The explanation may possibly be found in the combined greater age and superior vigour of the Jamaica plants. For, Mr. Morris goes on to say:—

The "fine root" bark was taken from trees about eight or nine years old and the price obtained was higher than for similar bark shipped during the year 1880, while the price obtained for trunk bark, classed as "fair branch," was slightly lower.

The twig bark classed as "good twigs" was obtained from young shoots and saplings probably not more than a year or a year-and-a-half old. These had to be removed to thin the plantations and to allow more space for the stronger shoots to grow and increase in size and value. For bark from these an average of 1s 4¾d per pound was obtained.

As the actual cost of barking, curing and shipping amounts to about 7½d per pound it is evident that even with such young growths as these there is fair margin for profit to the grower. The one bag of "middling twigs," which obtained only 7½d per pound, was sent merely as an experiment in order to test the lowest quality which could be remuneratively sent to the market. The bark was of a thin papery texture, obtained from the youngest and most succulent shoots. The "dust and garblings" were the sweepings of the barbecues and drying shelves, which, it will be noticed, obtained 1s 11d, and 1s 10d per pound.

A consideration of these sales will, I believe, show that, for good cinchona barks, the market has altered but very slightly and there is every indication that cinchona cultivation in Jamaica, if confined to the best kinds and intelligently pursued, has every prospect of becoming a successful and remunerative industry. I would add that this is the *third* crop of bark harvested by coppicing &c., from the New Haven Gap and Monkey Hill Plantations, and they are now in a good state of cultivation and likely to yield a succession of crops for many years to come.

This is, as far as I am aware, a fact unique in the history of cinchona cultivation.

Altogether it seems evident that if the soil and other conditions generally are equal to those of the New Haven Gap and Monkey Hill plantations, Jamaica is likely to run Java closely in the race of successful cinchona culture. The only qualification Mr. Morris makes, apart from red spider and thrip already noticed, is with reference to "some few denuded ridges where ruginous clay crops up." Mr Morris notices favourably the desire of the Jamaica Government to get cinchona febrifuge manufactured locally; but we suspect the better plan will be to sell their bark at good prices in the London market and then buy the various alkaloids from those who have devoted their lives to cinchona bark chemistry. After a paragraph on jalap cultivation, Mr. Morris notices a system of training cadets and apprentices at the plantations, which might, in a modified form, be worthy of consideration in Ceylon; although of course, the pursuit with us has already been taken up largely as a matter of private enterprize. Still young Europeans and Tamils might be taught a good deal that would be useful to them in our Government Gardens. We quote the paragraphs :—

CADETS—With the approval of His Excellency the Governor a certain number of cadets are being received, without salary, at the Government Plantations for the purpose of being taught the details of cinchona cultivation, and with the view of fitting them either to open plantations on their own account, or to act as Managers or Superintendents of cinchona plantations. At the present time three gentlemen are so attached, and I am glad to be able to report that they are devoting themselves with zeal and energy to their work and taking a keen interest in all that concerns the value and management of labour: details of nursery work: the minutiæ of planting: and the various methods adopted for successfully harvesting cinchona bark.

The knowledge and experience thus gained will doubtless prove of great service to them in after life, and I look forward to a great impetus being given to Cinchona planting by the introduction of men of captail and education who intend to devote themselves solely to this important industry.

APPRENTICES.—In order to train a number of the better class of native workmen in the details of nursery and propagating work connected with Cinchona cultivation, an attempt has been made to attach a certain number to the Government Plantations, where they undergo a systematic course, so as to fit them in due time to take charge of nurseries or act as foremen on private plantations. The experiment so far has worked satisfactorily. The apprentices for the first three months receive only a nominal rate of pay, which, however, is gradually increased as they become more efficient. When applications are received for men to take charge of nurseries on prive plantations, the best of these apprentices are recommended, and they generally receive wages ranging from 12/ to 20/ per week. Three men trained at the Government establishment have lately been appointed as foremen on private plantations, and four more are undergoing a course of training to fit them for such appointments.

By these means it is hoped the success of cinchona planting in private hands will be greatly promoted and at the same time an important service rendered to a large class of young men hitherto without the means of lucrative employment.

The cinchona plantations disposed of, we have next a notice of the Parade Garden, Kingston, 50 feet above the sea, with a mean temperature of 79·5 (1° below Colombo) and 43·18 inches rain (the rainfall of Jaffna nearly). This is a park and pleasure gardens for the good people of Kingston. What Mr. Morris says about the *Victoria regia* may, perhaps, account for failures with this Royal Water Lily in Ceylon :—

The Victoria regia (Royal Water-Lily) which flourishes with great luxuriance at the Castleton Gardens has often been tried in this basin but it has seldom grown for more than a few months. It is evidently destroyed by a small fresh water snail (Planorbis) which comes in the larval or young state in the water. A similar difficulty was found in establishing this handsome plant at the Ceylon Botanical Gardens and I doubt whether it can be wholly overcome.

We never heard the term "willow" applied to any of the Indian figs in Ceylon, but, as far as we can make out, our bo-tree, which might well be called the Indian aspen, is in Jamaica called "the Ceylon willow," and Mr. Morris values its ornamental character so highly that he has planted it (or some Indian fig) alternately with the Royal Cuba palm, in an avenue at the Governor's residence. The Indian figs (Urostigma) are thus noticed with other plants as growing in the Kingston Garden :—

Among the plants worthy of note in this garden, mention might be made of several species of Urostigma, which with their bright, green, glossy foliage and drooping habit are admirably adapted as shade trees for their plains. They have a rich profusion of small and somewhat thick leaves on numerous pendant branches, they stand wind well and never appear to suffer from drought. One species here commonly called the "Ceylon Willow" has been largely propagated by layering, and plants have been distributed to May Pen Cemetery and other places where handsome spacious trees are desired.

Two plants of Brachychiton populnea, allied to the Flame tree of Australia, are growing well and promise to become very ornamental.

A plant of Erythroxylon coca, propagated by seed from a specimen received about three years ago from the Royal Gardens, Kew, has within 18 months grown remarkably well and is now bearing seed. The leaves of this plant, it will be remembered, are largely employed as a masticatory under the name of Coca by the inhabitants of Peru, Quito and New Grenada. Coca forms an article of commerce among the Indians and wherever they go they carry with them a bag of the carefully dried leaves. [See Treasury of Botany, p. 469.] Among the plants of economic interest are two specimens of the Ceara rubber Manihot Glaziovi, which withstood the late drought much better than was expected; they are now growing rapidly and showing signs of flowering.

Among palms the indigenous Sabal umbraculifera, the Bull Thatch or Royal Palmetto, appears as would naturally be expected, to thrive well at this garden. A specimen only about 4 or 5 years old has flowered and fruited for some time and it is evidently at home.

The handsome and graceful Cocos plumosa: the glaucous-hued Date palm, Phœnix dactylifera: the Royal Palm of Cuba, Oreodoxa regia: the indigenous Mountain Cabbage, Oreodoxa oleracea, also add to the beauty of the garden and give it a characterestic tropical aspect.

If the Royal Palmetto is so much at home in Kingston, surely it would do well in portions of Colombo fairly sheltered from the monsoon winds? The Hope plantation is situated at 650 feet altitude, with a mean temperature of 78° and a rainfall of 56 inches, and of it Mr. Morris says :—

This establishment has been found of increasing importanee for tho distribution of economic plants in the plains; and Mr. McNair has steadily and satisfactorily met the numerous demands made for new sugar canes and for such plants as Liberian coffee, cacao, nutmeg, orange, pine apple, teak, mahogany, divi-divi, and other timber and fruit trees.

The celebrated Caracas cacao which, I believe, has now been introduced for the first time to Jamaica is likely to prove most useful for cultivation in warm sheltered valleys along the southern slopes of the island.

The elephant cane, the history of which has already been given in former reports, continues to be in great demand and is much liked in certain districts. It is evidently best suited for warm humid climates. In dry districts even with irrigation it is not so successful as the Salangore. With such varying conditions of soil and climate as exist on sugar estates in Jamaica, it may naturally be expected that numerous varieties of canes are required to enable the planter to obtain the best results with the means at his command. Hence, I look upon the greater interest which is taken in cultivating new varieties of sugar-canes and the

establishment of nurseries on estates as most hopeful signs of awakening in the staple industry of Jamaica.

A large collection of canes had been received from Mr. Horne of Mauritius one of which is said in the Sandwich Islands to yield 6 to 7½ tons of sugar per acre, or over three times the average! But this cane ratoons only once. We quote again :—

The selected varieties of cacao plants, numbering about 340, are in good health and have made rapid growth during the past year. Although planted out only about 27 months ago the largest are now 7 feet in height and measuring 7 inches in circumference at the base. Many have flowered freely, but in order to keep the plant in a good state of vigorous growth, they have not been allowed to bear at this early age. The temporary shade for these plants has consisted of a moderately thick growth of castor oil and banana; while young trees of the Sand box (Hura crepitans), Guango (Pithecolobium Saman), Jak fruit (Artocarpus integrifolia) as well as one or two of the *Bois immortelle* (Erythrina umbrosa) are already established so as to become the permanent shade trees.

The small blocks of Liberian coffee, nutmeg, clove, and cinnamon are also doing well, although they were severely tried by the drought. From observations at the Hope Plantations it would appear that Liberian coffee is quite unsuited to the Liguanea or any dry arid plains of a similar character even when well shaded; the plants continually suffer from "black bug" and have leaves of a sickly yellow tinge and show every symptom of feeble health. On the contrary, in the moister districts of the island, Liberian coffee looks very vigorous and healthy, as evidenced by their dark, glossy leaves, and the stout, robust character of their stems.

Similar remarks apply to nutmegs, which require very much the same conditions; and, if possible, the neighbourhood of a stream with deep alluvial soil.

The teak plantation occupying about ten acres is in good condition and forms an object of great interest. the trees are now between 7 and 8 years old, and, although planted in a gravelly soil, have made good progress.

The largest are about 40 feet high, with a circumference at base of about 26 inches.

It will be seen that there is, as yet, no evidence of *Hemileia vastatrix* having found its way to Jamaica.

The Palisadoes plantation is only 15 feet above sea-level and evidently on the sea-shore. The mean temperature is that of Colombo, 80°, but the rainfall, 39½ inches, seems too low for successful coconut culture. It will be observed that the superintendent, in describing the effect of the salt-laden winds on the young plants, applies the very language we used when noticing the effects of salt-storms on vegetation, with reference to the stem-mortification disease—"as if they had been burnt by fire." It will be seen also that the mungoose which has freed the sugar estates from rats is powerless against those climbing vermin on coconut plantations.

At this experimental coconut plantation, the chief operations have been the clearing of land for extensions on the eastern boundaries; supplying vacancies; the maintenance of nurseries; and general manuring and weeding. The number of young coconut plants put out in fresh ground or for supplying vacancies amounted to 2,371; the number distributed free to the admiralty for planting at the Morant Cays, and Port Royal, to the Commissioner of Turks Islands, and the Royal Engineer's Department was 1,750; while 200 coconut plants were sold to private plantations. The number of plants at present (Sept. 30th) in the nurseries, ready for planting out, is 3,135.

The crops of nuts obtained during the year was 33,380. This is the smallest return for some years and is attributed by the superintendent to the severe drought of last year which lasted for seven months—viz.: December, 1881, to June, 1882. For four months, of this time, he reports the prevalence of strong sea breezes with heavy spray which affected the general health of the trees "making them look as if they had been burnt by fire." To these I would add, the after effects of the hurricane of 1880, which did much more injury to this plantation than was, at first, anticipated. There is, no doubt, that although coconut trees can withstand moderately strong winds, they suffer for a long time if subjected to anything like a hurricane. The trees actually blown down and broken were in most cases irretrievably lost; but of the remaining trees many had their crop of young nuts so battered that they never ripened: while the snapping of their numerous rootlets caused by the heavy swaying of the trees during the gale retarded their growth and rendered them unproductive for a longer or shorter period in proportion to the injuries received.

I find that the experience of coconut planters at Morant Bay, and other parts of the island, visited by the hurricane, fully confirms this view, and the opinion of one of large experience is "that coconut plantations take fully two years to recover after such a hurricane as we had in 1880."

This view is supported by the decided falling-off in the general export of coconuts from this island during the past year. While in 1880 the number of coconuts exported from Jamaica had reached the large sum of 6,315,475, the exports for 1881 suddenly fell to 2,560,534, or about three-eighths of that amount.

The superintendent reports that during the drought, when there was a scarcity of fresh water on the plantation, the black rat, which is a tree climber, was very destructive to the young nuts, causing the loss of fully 20 per cent. of those forming on the trees.

Although the mungoose is plentifully distributed over the plantation, (and is often seen swimming across the salt water lagoons to reach the birds' nests on the islands) as it cannot climb, it is quite unable to reach the black rat which builds its nest and practically lives in coconut trees. The depredation caused by rats is not so apparent during or after rains as probably during such times they are not driven by thirst to attack the young coconuts.

King's House Gardens and Grounds are 380 feet elevation, with a mean temperature of 78·7 and a rainfall of 43·53 inches. In Jamaica, as in Ceylon, the guava plant seems to haunt waste grounds. Mr. Morris writes :—

The pasture adjoining the East Lodge has been thoroughly weeded and the ubiquitous guava bushes carefully rooted out. The guava is one of the most troublesome weeds in lowland pastures in Jamaica, and although horses and cattle are fond of the fruit and are observed eagerly searching for it on the trees, a pasture over-run with guava bushes has a most untidy appearance. Another troublesome pest in pastures is the guinea-hen weed, Petiveria alliacea, which, as it endures much drought, and remains green when other plants are burned up, is often eaten by cattle. It has been observed to give milk the taste of garlic and it is also said to communicate a most unpleasant flavour to the flesh of the animals feeding upon it. Other troublesome weeds in the pastures are Corchorus hirsutus and Triumfetta semitriloba.

As contributing to give the approaches to King's House a more cultivated appearance an avenue has been designed one chain wide on each side of the road which, this year, has received its first supply of plants. These, about 130 in number, consist of Urostigma, here called the Ceylon Willow, alternating with Oreodoxa regia or the Royal Palm of Cuba, one of the most stately and handsome of the palm tribe. A pit four feet wide and three feet deep was prepared for each plant and filled with two cart loads of soil well mixed with rotten manure and leaf mould. To prevent cattle from injuring the plants they have been enclosed by a circle of penguin about ten feet in diameter which, when fully grown, will form a cheap and excellent protection against all kinds of stock. The space between the avenue and the road is kept clean and closely cut.

Besides "the Ceylon willow," there is mention made of another Ceylon plant in the following paragraph :—

Among the trees and shrubs which were noticed in flower for the first time was Dillenia indica, the Hondapara of the Sinhalese, a handsome East Indian tree with leaves resembling the Spanish chestnut and very large white petalled flowers with yellow stamens. The Loquat or Japanese medlar (Eriobotrya japonica) also flowered at King's House for the first time, although in other parts of the island it has been established for some time. Among other plants worthy of note which have lately flowered mention might be made of Dipladenia amabilis, with its handsome cluster

of rose-coloured flowers, and the Gloriosa (Methonica) superba, commonly known as the climbing lily.

During the latter part of the year there was a decided improvement apparent in the general health of the trees with every promise of a good crop next year.

The Moringa (Moringa pterygosperma) plantation consisting of about 1,048 trees is in good order and coming into bearing.

Bath Garden, at the extreme end of the island, must be near the mountains or in the track of the rain clouds, for, although only 170 feet above sea-level and with a mean temperature of 79·5°, the rainfall is 96 inches, or more than twice that of King's House Gardens at an altitude of 380 feet. In the section headed "Cultivation and Distribution of Economic Plants," Mr. Morris writes :—

LIBERIAN COFFEE.—Continued attention appears to be devoted to this coffee in the moist lowland districtts of the island, where it promises to become an established industry.

In suitable localities—that is, at elevations not exceeding 800 feet, and with a mean annual rainfall not less than 80 inches—it appears to be a very robust and hardy plant, possessing great yielding qualities.

At the Castleton gardens, Mr. Syme reports that the small plantation established little more than three years ago is all that could be desired. The larger plants are bearing heavily, and now (October) ripening their first crop of cherries.

At Plantain Garden River estate, Mr. James Harrison, the enterprizing manager, has a very promising plantation of this large-beaned coffee in full bearing.

For pulping Liberian coffee, I notice that a very useful hand-pulper has been invented especially for this large-beaned coffee by Messrs. John Walker & Co., Colombo, Ceylon. It is said to pulp at the rate of ten bushels per hour, and cost complete eighteen pounds.

Another machine adapted for hulling this coffee in the "cracknel" state, that is, after the cherries have been dried in the sun (without pulping), is recommended by Mr. E. S. Morris, of Philadelphia, who has taken a great personal interest in the development of the coffee industry amongst the negroes of the Liberian republic.

CACAO.—There are very satisfactory indications that cacao planting is being generally taken up in Jamaica, and especially in conjunction with that of bananas.

I am unable to enumerate all the localities where cacao cultivation is being tried, but the following instances will indicate the chief centres of operation :—

In the Bath district, I am informed that Dr. Neyland, Mr. Hoyes, Mr. Harrison, Mr. Thompson, and others have, in the aggregate, "about 250 acres of cacao regularly planted and highly cultivated; but generally throughout the district cacao grows with great luxuriance, and in almost a wild state around the houses of settlers,"

As already indicated in the handbook on cacao cultivation, "cacao to be successfully cultivated in Jamaica must be confined for the most part to the moister valleys and hollows. Where the plains meet the hills, at elevations say from sea-level up to 450 and 500 feet, and where there is good shelter from prevailing winds, cacao should thrive well. The rainfall should not be below an average of 60 inches per annum, nor should the mean annual temperature fall below 75 Fah."

Again, "most of the cacao shipped, at present, from Jamaica is grown by settlers or small proprietors who are wholly unacquainted with the 'sweating' and curing processes: and hence the produce (simply washed and dried in the sun) is shipped in an inferior condition, and the prices realized are only one-half of what they ought to be."

Since the publication of the handbook I am glad to find that greater attention is given to the sweating and curing of cacao; and, as the cultivation is more generally taken up by Europeans, the day is not far distant when Jamaica cacao will greatly improve its position in the London market.

CARDAMOM.—This valuable spice plant, allied to, and having much of the habit of, the wild-ginger of this island, has lately been introduced to Jamaica with satisfactory results. It is adapted for cultivation in moist shady situations and at elevations ranging from 2,000 ft. to 3,500 ft. The plants may be put out at 5 ft. to 6 ft. apart and require little cultivation beyond keeping the ground clear of rank-growing weeds. The return, per acre, at the end of three years is safely estimated, in Ceylon, at about 170 pounds of cardamom seeds worth 4s per pound. Several hundred plants are now available for distribution from the Public gardens.

VANILLA AND BLACK PEPPER.—The cultivation of these plants is being gradually extended; but not nearly to the extent to which they deserve. To encourage their more general cultivation cuttings are now being supplied from the Public gardens, by post, accompanied by full details as to treatment and cultivation.

NUTMEG.—Continued attention is being given to the cultivation of nutmegs; and although every effort is made to keep up supplies of plants, in pots, at the Public gardens, the stock is still inadequate to meet the steady demand for this valuable spice tree. I fear numerous plants are lost in the island on account of want of attention to their requirements as regards climate and soil. It cannot be too often repeated that nutmegs require a warm, moist climate at nearly sea-level: a deep, rich alluvial soil in a sheltered position: and these conditions are much improved by the presence, in the immediate neighbourhood, of a stream of fresh water or a slow flowing river.

CINNAMON.—The plant of the best variety of Ceylon cinnamon, brought from Kew, in 1879, is now 7 feet high and in excellent health at the Castleton gardens. Several plants obtained by layering its branches have been put out in the experimental garden. Besides which a few are now established in pots ready for distribution. The stock of plants of the ordinary 'country" form of cinnamon is very extensive.

KOLA NUT.—This tree which has lately attracted considerable attention is common in many parts of the island under the name of "Byssi" and seeds can be obtained, in quantity, if required for commercial purposes. Dr. Neish, of Port Royal, to whom I am indebted for a note on this product, remarks: "What enhances the value of kola nuts at the present time is the fact that citrate of caffeine—a medicine now much employed for the relief of sea-sickness, megrim, and other nervous complaints—can be readily obtained from these nuts, for the reason that the nuts contain more caffeine than coffee berries: and in the kola nut the caffeine is in the free or uncombined state. These nuts are likely to take their place in the market as furnishing a nutritive and stimulant beverage. Rich in the active principle of coffee, containing also a large proportion of theobromine, the active principle of cacao, these nuts in addition contain three times the percentage of starch contained in chocolate: and, moreover, they also contain less fat, so that, in addition to stimulant and nutritive properties, there is the probability that a chocolate prepared from them will more readily agree with delicate stomachs."

The suggestion made by Dr. Neish that a chocolate might be prepared from the kola nut seems a very appropriate one, for both the cacao and kola belong to the same natural order, Sterculiaceæ, and the habits and characteristics of the two trees are very similar. They both effect low warm situations and in view of the probable demand for kola nuts, attention might very well be given to their cultivation.

That portion of the report dealing with table fruit we have already noticed, so that now we have only to quote what is said respecting

RUBBER-YIELDING PLANTS.—Of the African rubber plants there are four species of Landolphias, viz., L. Kirkii, L. Watsonii, L. Petersoniana and L. florida at Castleton which are growing well. They are scrambling twiners which require bushes or low trees for support. Of the Para rubber there is only a single specimen about 2 feet high at Castleton; it is in good health and likely, before long, to give its first crop of seeds.

The Ceara rubber trees, of which there are several specimens in excellent health, promises in every way to be suitable for cultivation in Jamaica. The largest tree is about 25 feet high, with a circumference at 2 feet from the ground of 30 inches.

The Castilloa or Central American rubber was introduced last year from Kew, and there are two plants of which one is in good health. Being a member of the

breadfruit family, this rubber-tree promises to be most valuable as a shade tree for cacao, and arrangements are being made to introduce seeds in large quantities, and distribute them for experimental trial amongst cacao planters.

PARA OR BRAZIL NUT.—This is now established in the island from seed obtained in May 1881. The Sapucaja nut (Lecythis Sapucajo) is also established and promises to prove a valuable acquisition.

TONGA.—I quote the following from the *Gardeners' Chronicle*:—

"TONGA, THE SPECIFIC FOR NEURALGIA."—Such is an an advertisement of Messrs. Allen & Hanbury's that has now been before the public for many months past. Tonga is a vegetable drug, and the material from which it is prepared is stated to consist of a mixture of bark and fibrous matter, the botanical origin of which was for some time unknown. It is now proved to be an ornamental climber, and a member of the Arum family with pinnatisect leaves in the adult stage, and large inflorescences, resembling those of a Monstera. Its medicinal qualities have been long known to the natives of the countries the plant inhabits. A few plants received from Kew, quite recently, have grown rapidly at the Castleton Gardens, and numerous specimens are available for distribution.

We suspect the Castilloa rubber plant will be found too exhaustive of the soil to be useful as a shade plant. That shade is necessary for the cacao seems to be taken for granted. Our readers will thus see that, in parting with Mr. D. Morris to Jamaica, we gave the West India island just the agent calculated to enable her successfully to compete with us in tropical agriculture. Dr. Trimen has not, like the Jamaica botanist, regular cinchona plantations under his care, but when his report is published we doubt not it will contain much of interest and value, both to us and to the our friends in island of the West.

PLANTING IN CEYLON HILL-COUNTRY: GENERAL REPORT.

COFFEE PROSPECTS IN HIGH DISTRICTS—ADVERSE WEATHER VS. LEAF-DISEASE—TEA AND ASSAM TEA PLANTERS.

Kandy, 26th April 1883.

I passed through the greater part of Dimbula, Dikoya and Maskeliya about ten days ago, and, with the exception of a few crack estates, I saw very little to cheer me. Crops will undoubtedly be short again unless we got a good May blossom, and this is, to say the least of it, unusual. Some blame the seasons, and I am myself inclined to agree with them. At any rate, to a certain extent, we *have* undoubtedly had far too much rain, and high coffee will not bear unless it has plenty of sunshine. A Ceylon planter now resident in the Wynaad paid a visit to Dikoya about a month ago, and in reply to an enquiry as to how our coffee compares with his, he said that it was immeasurably superior, and that he attributed his crops, which are always pretty good, to favourable seasons: they have no rain in the Wynaad worth speaking of for the first three months in the year, then come a series of blossoming showers and every branch bears. It is this sort of weather we want—not ten days fine and then showers every afternoon for another ten days. The appearance of the coffee in the young districts, excepting on grubbed estates, is as promising as one could wish, but it is impossible the trees can blossom with a rainfall such as has been experienced this season.

Leaf-disease is of course a terrible scourge, and one which may safely be blamed for many of our misfortunes, but they have the fungus in India as well as in Ceylon, and yet the crops from Coorg and Wynaad satisfy proprietors.* Who knows therefore what coffee may do for us when Mr. Tytler's wet cycle comes to an end, and we have the good old-fashioned seasons back again?

* Not last season: Coorg crops were nowhere.—ED.

But there are scores of planters who ridicule the idea of adverse weather being in any way responsible for short crops. They will lead you triumphantly to a field of young coffee bearing its 4 and 5 cwt. an acre and again to trees such as are to be found on places like St. Clair, Devon, Yoxford, &c., and ask you how you reconcile these results with the theory of unfavourable seasons. I admit the difficulty of the problem—the condition of the wood no doubt has a great deal to do with the diminished yield on most estates—but at the same time the gentlemen who profess to ignore the prejudicial effects of an abnormally heavy rainfall will find it very difficult to convince me that, had we experienced dry weather for the first two months of the year, crops even on the few crack estates we boast of would not have been very much better, and as for those less favourably situated, a dry season is, I repeat, essential, and it is what we always used to have.

The effects of rain on an open blossom are not in my opinion so serious as is generally represented, and, although it may appear strange to say so, I would sooner have rain than a broiling sun at this particular time. However it is not much use pursuing the subject. Unless something unforeseen occurs, we are to have another short crop, and planters I suppose will go in all the more strongly for tea. If the bushes only flush as freely as the coffee, we shall have very little to complain of: but will they? and will they stand this system of constant plucking insisted upon by Mr. Cameron?

We have several Assam tea planters in our midst now, and, seeing that Mr. Cameron was the first to recommend a ten days' plucking, why don't some of them come forward and tell us whether in their opinion we are right or wrong in adopting this system? It is one to which, I presume, they have all given a great deal of attention, but I don't understand these Assam planters—they are a complete puzzle to me. Either Mr. Cameron is right in concluding that Ceylon tea can be plucked away at constantly without doing the trees any harm, or he is wrong. If he is right, why were we not told so long ago by the Indian tea planters who have settled among us? If he is wrong and the theory is unsound, let them come forward and say so. One would think that the first thing a tea planter should learn would be how to pluck, and, if these Assam swells cannot tell us, what is the use of them?

Mr. Cameron tells us that some of the best estates in Maskeliya will yield 600 and 700 lb. of dry leaf per acre when the bushes reach maturity. I simply do not believe this any more than I do that a flush will be ready for the coolies every Monday morning, irrespective altogether of seasons and everything else.

However we shall soon have the views of another on this subject, for, if my information is correct, Messrs Cameron and W. B. Aitken are to address the members of the Maskeliya Planters' Association on tea cultivation generally at high elevations at their next meeting, and the planters in the neighbourhood are looking forward with interest to the occasion.

If I were present, I should ask Mr. Aitken point-blank: "Do you or do you not support the system of constant plucking advocated by Mr. Cameron?" But, as I shall not be there, put up a member of the Association to ask the question for me and note carefully the answer given. A. B. C.

INDIAN AND CHINA TEA.

Like many others out here, I have been much surprized at the remarks in yours of 22nd December, re the adulteration of tea, inasmuch as they are likely to lead the public to infer that Indian tea is adulterated. I have been planter now some 18 years,

and can truly assure your many readers that there is not the slightest foundation for such statement. I am interested, of course, in trying to get our Indian teas known at home; but I can also tell you that it would be simple rumination for us to adulterate, from two very obvious reasons. 1st. It would be more expensive to adulterate than to send out tea pure. 2nd. It would at once be found out, and be certain ruin to the man doing it, whether he be manager or proprietor. Your readers, of course, do not know that all our boxes are conspicuously marked, either by the garden name, or its monogram, and can be recognised by the trade, and the slightest attempt at any tricks would become at once, widely known, and the man or garden marked and ruined. But the most conclusive proof that we do not adulterate is that it would cost more to do it than to make our teas pure. It is not as though we were short of bushes or leaves. Most planters know to their sorrow, that we are so short-handed that it is often more than we can do, to take off the so-called "flushes" of young leaf on our gardens, without searching for other leaves in the jungles. The best tea-seed is R150 per maund of 80lb., and 20,000 seeds, say 100 seeds for one shilling, and as the one maund will plant out five acres, the cost is simply nominal. Our land again at its highest rates is only 4s. per acre per annum, so neither of these items are worth speaking about. If your readers could see a tea garden (and they run from 50 to 3,000 acres) a huge clean sheet of bushes in rows, 3ft. to 6ft. apart, and the leaves all out in a flush, and people at their wits' end to get the leaf off, they would properly laugh at the idea of searching for jungley leaves in the forest at ten or twenty times the cost. Coolies pluck 16 lb. of young leaf (which alone will roll) as the day's task, but it is so easy that they do extra, for pice, and average 30 lb. to even 60 lb., and this leaf stands us in about 4 lb. a penny; and it takes 4 lb. of the "green leaf" to make 1 lb. of dry tea, the collecting only costs us, say, 1d. per lb. (It is generally far less.) Next I may tell your readers that, though I know these forests well, I don't, so far, know a single leaf that can be confounded with a tea-leaf, and to be able to get them at all cheap, they must be planted and in the open; ergo, why not plant tea at once? Tea and tea planters are in a bad way now here, but it is not from want of leaves; we are suffering from an overstocked market; production has so outrun demand that it has doubled in a few years, and our prices are fallen so low that many estates have now for two years been worked at a loss, even though we now make our teas on the garden at 6d. per lb., all costs in, and all classes alike. Freights are high, and it takes as much to send our teas down to Calcutta as thence home. The freight of plain iron work up from Calcutta by river steamer is equal to the freight from home plus the cost price of the iron. Again, we planters are in the middle men's hands. We suffer from "rings," and to crown all, the men who sell for us are also the men who buy for the home trade. Can you wonder we are short at our last gasp, and long to sell direct to the grocer or consumer? In my last sale but one, the "Pekoe," equal to what the great advertising firms sell at 3s only realised 10d and as another 10d would pay duty and freight home, there is a huge profit made by these people, or the middleman, and neither the planter who has the hard work in the jungles nor the English mechanic get their share. A few men are making huge fortunes out of us, especially the small concerns. The extraordinary and barefaced lies that are told the public by the great advertising firms are simply appalling—about the best tea being off the first flush of leaf. It is the very opposite; the first flush is always nearly destitute of "tips" (or the little bright unrolled buds), and our "flushes" come out about every 12 or 16 days, from May to October, the best in July or August. The comical "rot" about sweeping up the "fallen leaf," rotten, smothered in mud, and only seen when our season is over, is—well, it's painful for a planter to read. Again, there is, not a single firm at home, who get their teas plucked for them to order; it is absurd, but the public unfortunately can't see that it is as absurd as a hotel-keeper gravely saying he had a particular turbot grown for his customer in the North Sea. Last year and the one before a small quantity of tea from specified estates has been "bulked"—i.e., mixed for the Australian market, but it was and is a necessity there, so as to elucidate slight differences and be able to send a steady quality always. This is easily understood. Again, your readers, perhaps, don't know that all our Indian teas, without exception as far as I know, are sold from the report of valuation of leaf and liquor. We dare not adulterate. If it is done, it is only possible after it leaves bond in England, and the chests are opened by the middle-man and dealer, or grocer; and here it is we have cause of complaint, as the public never taste our teas pure; they are always mixed with "China," unless got direct from the estate and in original boxes with garden mark. This "mixing and blending" with China may be a necessity in a transition stage from pure China teas to pure Indian; none the less, it is not done here for the home market—cannot be; and as for using other leaves, it is a gross calumny. I defy anyone to prove such a thing of an Englishman, or any English firm. Nay, more, I am certain planters, though none too well off, would gladly contribute for a big bonus to anyone who could prove such a thing. The absolute purity of our tea is our only hope—our sheet anchor. We may have hard times occasionally, and many of us sink under our difficulties; but none the less, we must hold on—the right road, and we shall win, in the end, and China die out. I can send you all about home plant, and "pluck" roll, and sift and pack if you like; but first I protest against the lies told of us. It speaks volumes that the men who sell our teas for us in Calcutta positively decline to let us know who purchased them, or the prices they realised at home in England.—S. E. PEAL, tea planter, Aideo, Sibsagar, Assam.—*English Mechanic and World of Science.*

FIBRES AND FIBROUS MATERIALS:

CHINA (RHEEA) GRASS; ALOE AND OTHER FIBRES.

There is no limit to the experiments as well as the writing which the wealth of fibrous material or of raw material of supposed marketable value, provokes. The way in which information accumulates is most perplexing. A great deal of it may be of little value, because repeating an old story or taking up a substance, the marketable unfitness or unprofitableness of which has over and over again been demonstrated. This accumulation of material which has had to be weeded out is our excuse for not acknowledging and publishing some papers of interest with which we have been favoured, and which have been lying by for a considerable period. First, we are indebted to Mr. Kay-Shuttleworth for some papers referring to China grass as cultivated and the product manufactured in Northern Italy, with samples obtained when on a visit to San Remo towards the end of last year. These samples of the smooth silky fibre in its natural colour, and of the same smooth fibre coloured to all shades of the rainbow, rivalling silk in its fineness and beauty, together with samples of cloth manufact-

ured from light tweed up to heavy cretonne and damask, have excited the interest of scores of visitors who have seen them on our table during the past few months. Our correspondent's thought was that China grass might prove a useful "new product" for Ceylon, and perhaps grow freely and profitably on abandoned plantations. "It is such an exceedingly *simple* cultivation (in North Italy) and from the price, the machinery is so easily within the reach of small capitalists." It seems that the capitalist who has given the start to a new industry in North Italy is M. d'Humières, a Frenchman, who after residing in Java for some years, where he owns estates and where of course the Rheca (China grass) grows freely, retired from the tropics and bought the sole use in Italy of French patent machinery for the manufacture of Rheea fibre. M. d'Humières hopes to make money by growing and buying the grass from the Italian cultivators whom he supplies gratis with plants under an agreement, the substance of which is mentioned in the following extract for which we are indebted to Mr. Kay-Shuttleworth :—

Urtica (*Urtica tenacissima**)—(*Eng., China grass ; French, Ramie.*)

(*Translation of article in the "Corriere di San Remo" of September 10th, 1882.*)

We would commend to the attention of agriculturists a tact which may be of considerable and beneficial importance to Italy and especially to the Riviera [coast between Marseilles and Genoa]. M. d'Humières has imported into this district the cultivation of a new plant, which flourishes in our climate and yields abundant and excellent crops.

The plant, of which M. d'Humières owns large plantations in Java, and which he has undertaken to cultivate here at San Remo and in other places in Ligaria, is a *textile plant*, Urtica tenacissima, indigenous in India and China. It grows wild in Java. It is easily acclimatized in temperate latitude and grows in *any* soil, but flourishes best in light, sandy and alluvial soils. Its cultivation is easy and simple and it yields four crops in the year.†

Its form is that of a shrub with stalks from 1½ to 2 meters in height. The stalks are as thick as one's little finger at the root, straight and smooth. The textile fibre is covered with a thin bark ; when this has been carefully removed, there is a mass of long threads, silky and very strong, admirably adapted to all the requirements of manufacture. When bleached these threads are shiny like silk. In the East this fibre is called vege able silk.

When combed and treated in the same manner as Australian wool it can be spun very fine and can be mixed with cotton wool or silk and dyed any colour or pattern.

Eastern nations have used it for centuries in their peculiar silky stuffs; in their cashmires and nankeens, they introduce a certain proportion of these vegetable threads. These stuffs owe their consistency and softness, the secret of which European manufacturers have vainly sought to discover, to the admixture of China grass in their composition.

But this is not its only use. Its principal quality is tenacity (hence its name, tenacissima). In the Sunda Islands, its original habitat, cords, fishing nets and very solid sails are made of it, and it is particularly well adapted to these uses, being watertight. The light strong fishing nets which come to Europe from China are made of this fibre.

China grass is beginning to be used in Europe for several industries. Every part of it may be utilized —the remains of the stalk, after the fibre has been extracted, contain tannin—the leaves are fibrous like the stalks and useful for paper-making, besides being excellent food for cattle.

The Urtica tenacissima is a perennial plant, like the bramble ; it springs up again from the roots.

The useful qualities of this plant are so highly esteemed by the Dutch Government that it has appointed a commission to study the advantages and drawbacks attending its cultivation. In 1870 the Minister of Commerce and Agriculture in France appointed a similar commission. The English Government [of India], convinced of the important part that this plant will some day play in industry and commerce, has offered a prize of £5,000 for the best system of extracting its fibre. Much more might be said about this plant, but the above will suffice to prove that its cultivation in Italy will be of great service to our national agriculture and industry, and especially at the present day, when England, France and Germany have established manufactories in which they use it, and draw their supplies from China alone in sufficient quantity for their requirements. We propose to return to this subject on a future occasion, and only wish to call attention in this article to the excellent results which M. d'Humières has obtained in our soil and in that of other places in the Riviera.

From the experiments we have witnessed, it results that the climate of Liguria is preeminently favourable to the cultivation of this article, which yields four crops a year here, while in Egypt and Algiers it only yields three and only two in France, and it must be observed that it is a much richer crop than flax or hemp. In about a fortnight 200,000 plants will be cut that were planted in June in a garden of San Martino. Signor Calsino has started another small plantation which is prospering very well in the locality called Cadorso.

At Loano, where M. d'Humières has taken 300,000 square metres of land on a long lease, he has lately planted more than a million young plants, of which a large part is put at the disposal of agriculturists who are inclined to try this new crop. On this point we are moreover authorized to state that M. d'Humières will spare nothing to encourage and help them in this new enterprise. He will instruct them with his counsels, give them moral and material help, put at their disposal the necessary quantity of plants, contracting to buy all their crops at a price which will offer them large profits. Sole possessor of a machine newly invented for peeling and bleaching the fibre, M. d'Humières is in the most favourable position for giving this new agricultural industry an impulse such as may work a beneficial revolution in this district.

Notes on above, after a conversation with M. d'Humières.

The Urtica, an indigenous variety, is used by the Sinhalese for nets, and I believe grows from a low elevation to 5,000 feet in Ceylon. The "China grass" is exceedingly easily cultivated, and is growing freely at San Remoin the stiffest of clays. It grows from root cuttings. 4 lb. of dry stems give 1 lb. of fibre. The fibre sells for about R1·37 per lb. or £6 per kilo. In the cotton districts of America and Egypt it is being substituted for cotton.

The machinery is a French patent, and a machine capable of turning out 225 lb. of clean fibre per diem costs about *f*2,000 or R1,000, weighs 250 lb. and measures about 4 square metres. M. d'Humières showed me some fibre in the rough and bleached, also various fabrics, sail cloth, calico, a kind of serge, and mixed fabrics, besides a piece of cord made of it. The plant is a bush throwing up 40 to 80 shoots about 5 feet high, which are cut periodically. The cultivation appears to be thoroughly suitable as a substit

* The better known botanical name for the Rheea is *Bohmeria nivea*.—Ed.

† This applies only to the most favourable places ; in her places it yields only 2 or 3 crops.

ute for lantana or old coffee, and seems worth thorough enquiry in all quarters.

The outlay for such a culture in Ceylon appears to be very small. Unlike coffee and other products grown by planters, the Urtica gives a speedy return, and apparently promises a large one, but it remains to enquire more closely into figures. If the Urtica gave only R200 worth of fibre per acre, the profit would be very large, as from the conversation I have had with M. d'Humières I believe it to be, but I hope to get more information shortly, and send it to you. My object is to direct attention to this apparently good new product, as a remedy for abandoned or worn-out coffee to take the place of lantana and scrub, if not as a regular new product for new lands.

Wages here are R1·50 for men R0·75 for women, and if in this comparatively dry climate with such wages as these the cultivation is profitable, can we not with cheap labour and a foreing climate grow what is so profitable here and in *Java*? It could be worked by contract, the attention required being merely to cut the shoots at the right times, and bring them to the store, care being taken not to injure the younger shoots.

But I hope to send more detailed information shortly. This letter must be looked on merely as an introduction to the subject, and I hope that it may prove useful to my fellow planters, who may perhaps get more local information from Java, China, India, etc., and enquire carefully into the subject individually.

S.

San Remo, Italy, Nov. 25th, 1882.

It may be as well to give at once here what is said of the Rheea in the "Treasury of Botany":—

Bohmeria. This genus of theorder of nettleworts (*Urticaceæ*) contains numerous species distributed throughout the tropics and subtropics of both hemispheres. They are herbaceous plants or shrubs, closely allied to true nettles (*Urtica*), but differing from them in not having stinging hairs. The male and female flowers are produced in separate spikes on the same plant: the males having a four-parted calyx and four stamens, the females a tubular calyx divided into four teeth at the top, and a slender style with hairs along one side. Several of the species yield valuable fibres. The most interesting of them is *B. nivea*, the Tchou-ma of the Chinese, the Rheea of Assam, and the Chinese Grass-cloth plant of English writers. It is a small shrubby plant about three or four feet high, throwing up numerous straight shoots, which are about as thick as the little finger and covered with short soft hairs. Its leaves grow upon long hairy footstalks, and are broadly heart-shaped, about six inches long by four broad, terminating in a long slender point, and having their edges cut like a saw. They are of a deep green colour on the upper side, but covered on the under side with a dense coating of white down, which gives them an appearance, like that of frosted silver. The beautiful fabric known in England as Grass-cloth, and rivalling the best French cambric in softness and fineness of texture, is manufactured from the fibre obtained from the inner bark of this shrub, which is a native of China and Sumatra, and has long been cultivated in those countries and also in India, where it has recently been recognized as identical with the Rheea of Assam. The Chinese bestow an immense amount of care and labour upon its cultivation and the preparation of its fibre; they obtain three crops of the stems annually, the second being considered the best. To obtain the fibre the bark is stripped off in two long pieces and carefully scraped with a knife, so as to get rid of all useless matter, after which it is softened and separated into fine filaments, either by steeping it in hot water or holding it over steam. The fibre is of different degrees of fineness according to the age of the plant, and the part of the bark from which it is taken: the inner bark of young quickly grown stems yielding the beautifully fine delicate fibre from which the best fabrics are manufactured, while the outer portion affords a coarse fibre only fit for making ropes, canvas, etc. Experiments made with the view of testing the strength of this fibre have proved it to possess nearly double the tenacity of Russian hemp.

B. Puya, which is a native of Nepal, very closely resembles the preceding both in its botanical characters and general appearance. It is, however, rather taller, growing as high as six or eight feet, and its leaves are of a different form, being broadly lance-shaped, and terminating in a sharp point; but they have serrated edges, and are silvery on the under side as in the last. This plant is called Pooah or Puya in Sikkim and Nepal, and its fibre has long been in use among the natives; but they have hitherto employed clay or mud in its preparation, which greatly deteriorates its value. When properly prepared it is very strong, and makes good cordage and sailcloth. Of the other species of this genus we may mention that the inner bark of *B. albida* is used in the Sandwich Islands for making cloth; and *B. candata* is employed medicinally in Brazil.

To be continued.

NEW AND OLD PRODUCTS IN CEYLON.

For 30 years coffee reigned king in Ceylon; no other product was dreamed of by the enterprizing European. There is now a danger of running into the opposite extreme and producing merely a numerous array of *samples*—a thing that never pays. Well it would be for all concerned if a few products could be fixed upon at as early a date as possible and gone into on sound commercial principles. An estate producing samples of a dozen different products is less likely to pay than one restricted to one or two.

I am glad to note Mr. Cameron's opinions of Rakwana and Morawaka as tea districts. I had for 15 years better opportunities of knowing these districts than most men, and have long been of opinion that the only known products that would pay in such localities are tea and aloe.

It is of course difficult to speak particularly of any district without trampling on some sensational fellow's toes, but time and money will be wasted in attempting cocoa or even cinchona in a district so varied in soil, climate and shelter. Patches of any tropical product may be grown, but patches do not pay. With the ridges however planted with aloe, now becoming so valuable for fibre, and tea in the sheltered valley, the old Rakwana range might yet rejoice. The aloe has the advantage over any other plant of actually improving the soil in which it grows, and, while pointing its own hardy leaf fearlessly to the S. W. monsoon will help to shelter the tea.

HISTORIC NOTES ON TEA.

Some interesting information on this head is furnished in a newly published work by the learned Swiss botanist, professor A. de Candolle. A legend, originally related by the Dutch traveller Kœmpfer, of a Buddhist monk, who came to China from India some time during the fifth century of the Christian era, and, in vexation at having slumbered during a night of vigil and prayer, cut off his eyelids, whence, forthwith, sprang up two teaplants, has often been repeated in popular works as not only prefiguring the anti-somnolent properties of the leaf, but as affording traditional evidence of the source and probable period of introduction of the tea plant into the Flowery land. Unfortunately for this view, the legend, it seems, is wholly unknown in China, whilst the plant itself has been known there from ages far more remote. Dr. Bretschneider, physician to the Russian Legation, Pekin, who has made many valuable researches in Chinese literature, states that tea is mentioned 2,700 B. C. in a Chinese compilation known as the *Pen Sao*, and likewise in another, the *Rhya*, which dates from 500 B. C. to 600 B. C., whilst a native commentator on the latter work, writing A. D. 400, gives full details of the plant and of the modes of infusion still in use. Its antiquity in China is therefore very great.* In Japan it may be of later introduction;

* We should like to know what learned Sinologists have to say to this assertion? The *North China Herald* editor has expressed scepticism regarding the alleged great antiquity of tea in China.—Ed.

but neither there nor in Cochin China, where it is probably of high antiquity, is there any tradition of its introduction from India. Its name is unknown in Sanscrit, as in the various dialects of modern India. The cultivated plant spreads its seeds readily, and thus runs wild—*verwildert*, as the German botanists say—so that naturalists are much at variance as to the actual spontaneity of the specimens alleged to have been found growing wild in different parts of China and Japan. A better established fact appears to be that the plant has been found, in an apparently indigenous state, by English travellers in Upper Assam and Cachar.

M. de Candolle, who treats the plant as a distinct botanic genus, not, as some naturalists are inclined, as a species of camellia—believes its native home to be the mountains on the south-west of China, which separate the great plains of China from those of India. Thence, in remote times, its use spread into China, but—strangely enough, considering the success which has attended its recent introduction in Assam—not in the direction of India. He likewise notes a curious incompatibility between the tea-plant and the vine, in which speculative advocates of total abstinence might find a suggestive theme. The two are never found together. In a few spots, like the Azores, it is true both tea and vine are grown; but these have been experiments on a small scale, and plants thus tried often prove unremunerative when tried on a larger scale. China has the vine, but it is little cultivated. China, Japan, Assam, and next to them, Ceylon and Java—these are the great tea-growing countries of the world. None of them grew the vine to any extent, if at all. On the other hand, Australia, the Cape, and other countries which promise to make their mark as the vine-producing countries of the future, are unfitted by drought for the cultivation of the tea-plant.—*Grocer.*

DR. TRIMEN'S REPORT FOR 1882 OF THE CEYLON ROYAL BOTANIC GARDENS.

Now that Colombo is the mail port and the great steamer port of the island, we are not surprised to learn, what the Director states, that there has been a large increase of visitors to the central establishment at Peradeniya and to the Tropical Gardens at Henaratgoda. When the railway is open to Nanuoya, we have no doubt travellers from Australia, India, and elsewhere, will be making pilgrimages to Hakgala, not only to see the site where cinchona culture was commenced in Ceylon, but to complete their enjoyment of beautiful and varied scenery by a view of the grand panorama of mountains, forests, patanas, rice fields and river-stretching away over the principality of Uva. We are glad, therefore, to learn that much has been done and is being done to add to the natural beauty as well as the economic value of the various gardens. It was only to be anticipated that with the occurrence of "hard times" the revenues of the gardens should fall off, from fewness of purchases and paucity of purchasers. But we must remember what the establishments have done for the interests of the island in the past, what they are doing in the present to help us to overcome depression, and what we feel certain they are destined to do in the future in accelerating revived prosperity, by introducing and supplying information regarding "new products." The cost of the Ceylon Botanic Gardens in 1882 was R37,824, of which about ten per cent was recouped by sales. It does not seem that this included the amount realized by sales of cinchona bark, a total from the first of R4,529. In looking at the total cost to the colony, we must not fail to take into account the fact that a sum of over R2,000 is included on account of upkeep of the beautiful Pavilion Gardens, portions of which are open to the public and which add so much to the attractions of Kandy. We do not envy the mountain capital its good fortune in having one fine public garden in its centre in addition to the beautiful river-encircled garden, park and forest combined at Peradeniya, but we must put in a strong plea for a distinct government establishment in the real capital of the colony. We are not forgetful of what the Municipality have done (the growing of plants and trees being a labour of love to their Superintendent of Works), or of the extent to which they have been aided by gifts of seeds and plants from Government; but surely Colombo is entitled to a separate Botanic Gardens of its own, in which visitors with only a day or a few hours at their disposal could see representatives of all the leading plants which flourish on or near the seashore. We believe a site with suitable soil could be found in the Cinnamon Gardens, at Wellewatta, or elsewhere. The capital of the North-Central Province is to have a Botanic Garden of its own, and we should be glad to see the capital of each of the other provinces of the island equally favoured. Money devoted to such purposes is never thrown away, for we have to consider not only the profit to the country by the successful introduction of new plants, but the refining and humanizing influence on the people of a well ordered collection of plants and flowers to which they can have constant access. Visitors to continental India cannot but be struck with the existence at every station of importance of Public Gardens which, in the name, still retained, of "Company Bagh," preserve the traditions of that eminent body of English traders, who, beginning as merchants, developed into statesmen and warriors and gave Britain ultimately the grandest empire which the world has ever seen: an empire in which all the productions of every clime, as well as most of the world's races, are meeting and flourishing. In the forefront of agricultural and horticultural enterprise has been and will be this "India's utmost isle" of ours, and ere long we have no doubt we shall take good rank in attention to arboriculture. We now await with interest the appearance of Mr. Vincent's elaborate Report on our Forests, to which Dr. Trimen alludes and which we have no doubt will prove as useful as it will be interesting.

For the right cultivation of forest trees as well as for the successful establishment of plants in Botanic Gardens, a knowledge of the main characteristics of climate is indispensable. Our readers will, therefore, be as much surprised as we are to learn that, although so long ago as 1861 Mr. Clements Markham chose, for the initiation of the experiments connected with the introduction of the fever plants to Ceylon, the plateau under the rock summit of Hakgala, because of the general resemblance of the natural features to those which distinguish the habitat of the cinchonas in the Andean ranges, yet, in the whole interval of twenty-two years, no regular meteorological observations have been taken, until Mr. Nock took to counting the number of rainy days. It is just possible that, as observations were regularly taken near by at Nuwara Eliya, two stations in such close contiguity were not deemed necessary. But Hakgala although not very distant in a direct line is in a different position as regards the vast plains of Uva, and faces the east, while the site of the Gardens is 600 feet below Nuwara Eliya Plain. The observations which Mr. Nock has been able to take seem to prove that the mountain plateau receives as much rain as the mountain plain, Mr. Nock's experience has been that rain fell at Hakgala in 1882 (a specially wet year) on 235 days out

of the 365 ; in other words there were only 130 rainless days in the year. In the ninety days between 25th June and 23rd September, rain fell on every day except one. No wonder if at Hakgala as elsewhere numbers of plants perished from the effects of persistent wet, which in high altitudes means persistent cold. Such seasons as we have recently experienced remind us of the old Scotch gardener who said the reason good apples, pears, strawberries, &c., could not be grown in tropical regions was owing to deficiency of heat! He was right in this way :—We have fierce heat here occasionally, but it lasts, at the utmost, not quite ten hours in the twenty-four, while in northern regions during summertime the sun scarcely sets for three months. Recently, however, excessive rainfall seems to have diminished summer heat in temperate regions as much as in the tropics. We may rely on it, however, that the sun will in due time reassert his genial influences. Meantime we would point out that, in Ceylon, at least, forest denudation has not diminished rainfall ; while neither here nor elsewhere on the earth's surface has the comet produced excessive heat. At Hakgala high winds occasionally approaching hurricane force accompanied the heavy rains, from middle of May to middle of September, just as was the case at similar altitudes in Upper Dimbula. We have no doubt a set of meteorological instruments have been or will be supplied to Mr. Nock ; but meantime, judging from analogy, we are safe in assuming that the mean temperature of the Gardens at 5,600 feet cannot be higher than 60°. A good deal of forest has been left for shelter, but on the other hand the wind, obeying the same general law as water, must come tumbling and tearing down the rock face, from the summit which is 1,400 feet higher up. On the whole, although shelter cinchona nurseries have succeeded well at Hakgala, it does not seem suitable either in soil or climate for the establishment of experimental plantations of the various kinds. With a change of seasons, however, Mr. Nock may have a better account to give. It is curious, however, that Dr Trimen, who mentions leaf-disease and grub, should have said nothing respecting the two cankers, root and stem, which have proved so fatal to cinchonas during the past severe season. Neither does Mr. Nock, while recording the "dying out" of Ledgerianas, say anything about the disease, if specific disease there was. What the Doctor says about grub, however, deserves to be noted by planters and scientists like our good friends Messrs. Cantlay and Dixon, who give the cockchafer "cusses" credit for attacking only unhealthy roots! On the other hand be it noted Dr. Trimen's reference to the virulent prevalence of *hemileia vastatrix* referred to 1882. There is a general feeling that things have improved in 1883. We shall soon know. In part of Netherlands India, we observe, the fungus is exceedingly destructive. The misery of it is that, after the experience with Liberian coffee, planters have so little encouragement to try superior coffees, like that recently coming to the front in Brazil. Like the Jamaica Blue Mountain kind, it would probably be attacked by the fungus as soon as it got above ground.

Dr. Trimen's notices of Arabian coffee and its chief enemies, fungus and grub, are not encouraging. On the other hand, he states that Liberian coffee, although badly attacked by the fungus, continues to yield good crops. Now that the local demand for seed has abated, and that this kind of coffee will make some figure in our exports, it would be well if it were separately specified in the Customs returns. We can, however, understand the objection of growers to describe their export as Liberian, while a prejudice exists against this "new product" in the London market. The very reverse feeling exists as regards Ceylon-grown cacao, the seeds of which are in such demand that the article will not for some time make any great figure in our export trade. Dr. Trimen's account of the varieties cultivated in Ceylon is interesting, and it is fortunate that the one which has been longest in existence in our island is of good quality. This industry is advancing, but Dr. Trimen regards cinchona as at present the foremost product of Ceylon. What the Director says about the growth of inferior kinds has, however, to be qualified by the fact that the range of climate and soil for Ledgeriana is limited ; while bark of the succirubra, when repeatedly renewed under Mr. Moens' shaving process, vies with the yellow barks in quality. The true policy, therefore, no doubt is, for all who can, to grow Ledgeriana, and for those who cannot, to devote their attention to succirubra and the robust hybrids or varieties. Dr. Trimen adds another answer to his own argument in favour of the superior kinds by showing how febrifuges composed of the secondary alkaloids are increasing in favour and in use. Amongst the millions of Eastern Asia, as well as the fever-smitten inhabitants of the Russian and American swamps, in the armies of the nations, and in all places where malarial fevers and debility afflict humanity, there is enormous scope for the use of the cheaper alkaloids of the cinchona barks. We know that English physicians have a prejudice in favour of sulphate of quinine, and we have heard that the German doctors have an equal prejudice against cinchonine ; but we believe all candid persons, including doctors who have fairly tested the drug, will acknowledge that cinchonidine, in which our high-grown officinalis, and especially our red barks, are rich, is little, if at all, inferior to quinine in therapeutic value. Objections on the score of occasional nausea we regard as of little consequence, because emetics are frequently curative of fever. But, we believe, this nausea objection has been greatly exaggerated. Dr. Trimen deprecates the practice of shaving very young trees, of which the poor planters will say : "My poverty but not my will consents," and our readers will recollect that we recently quoted the opinion of a planter who had devoted much attention to cinchona culture, that the shock to comparatively young plants by the shaving operation is less than in the case of mature trees. In most cases, however, we suppose, 3½ to 4 years from planting out should be allowed to elapse before the first shaving is performed. We are glad to observe that the Pitayo species has been introduced. We made an unsuccessful attempt in 1877. The plants we saw growing on Dodabetta had foliage comparable to that of Liberian coffee, and we were told that this was the hardiest of all the cinchonas, growing on the Andes up to 10,000 feet altitude. If this is correct, the plant ought to flourish in our alpine regions in Ceylon. The "hard Carthagena" and the plants which yield cuprea bark have also been introduced. In the latter case, the plants, which were understood to affect low levels, were growing at 6,000 feet altitude. If the cuprea bark trees are really worth cultivation, it may be taken for granted they will receive every justice in Ceylon. They are not true cinchonas, but they yield precisely the same alkaloids, while the barks appear to be easily operated on by the chemist. The great objection to the bark (original) of the succirubra is found in the large proportion of tannin and colouring matter which exists, and which renders the extraction of the alkaloids a difficult task. For decoctions, however, we believe, the tannin is valuable rather than the reverse, and we should think that chewing succirubra bark might be remedial in cases of diarrhœa ? Let us hope that the "morada" and "verde" varieties of calisaya (?) may meet the expectations formed of them. Dr. Trimen does not say much about tea, and he mentions only one timber,

the toon (*Cedrela toona*), as suitable for tea-boxes. As we have already pointed out, this cedar is only too good (that is, likely to be too expensive) for the purpose. Dr. Trimen, writing, we suppose, of plants grown at Peradeniya, gives a most encouraging account of rapid growth, but our readers may remember the record of Mr. James Taylor's experience, whose *toon* trees were destroyed by insects. Of course, locality may have had something to do with this. The Forest Department ought certainly to give a full trial to the cultivation of this most valuable timber tree. When in Java we found it the object of great attention on the part of Government and planters. It was being planted in immense numbers alongside the public roads, and in this connection we may mention that succirubra plants were so plentiful and so little valued for bark purposes, that they were being used as nurses for this and other valuable forest trees : that is, the succirubra plant with its broad luxuriant foliage was used to shade the forest tree seedling until it was beyond danger, when the nurse was removed. We do not know if this idea is likely to be of value in re-afforestation operations in Ceylon.

The information regarding rubber-yielding plants is interesting and useful, and we trust that ere long every tree yielding "indiarubber" or the gums called "gutta percha" will be at home and flourishing in Ceylon. It is interesting also to learn that attention is given to jalap and other medicinal plants, some of which it may pay planters to grow. In all such cases a considerable and expansive demand is a *sine qua non*. We had received the impression that the lichen, "orchella weed," which yields a fine dye, was especially plentiful on the stems of coconut palms. It was on that account, we understood, that the late Mr. H. Mead chose the neighbourhood of Kalpitiya as the scene of his collecting operations ; but Dr. Trimen merely mentions the trunks of trees generally. As regards fibre plants, we think it is time the common plantain, with only about 2 per cent of fibre to nearly 98 of water, should be left out of court, while the true aloe which grows on the seashore in the dry districts, is surley too soft and succulent to yield fibre ? Dr. Trimen was very successful in a collecting trip to the arid region in the neighbourhood of Hambantota, and the general herbarium is making good progress. The museum of economical products is only in the early stages. Ought not duplicate sets of the herbarium and museum specimens to be placed in the central Colombo Museum for the instruction of the thousands who can never enjoy the pleasure of a visit to Peradeniya ? and ought we not soon to hear that a popular Botany of Ceylon is well advanced ? We have waited long for this Handbook, while neighbouring colonies have long been supplied with descriptions of their "Flora." Thwaites' *Enumeratio* is a learned book for learned men. A book is desiderated which can be "understanded of the common people": newspaper editors and the like.

Believing as we do that Ceylon should largely imitate the policy of Switzerland by making the country as attractive as possible to tourists, nature having already done so much, we are glad to see that under Dr. Trimen's régime the fame and attractiveness of our Public Gardens is not likely to suffer, but rather to be enhanced, and we entirely approve of liberal expenditure in directions calculated not only to gratify professional botanists and meet the demands of agricultural industry, but to excite the admiration of travellers and visitors who, though neither botanists nor planters, have a keen sense of what is grand and beautiful in the garments, composed of trees and fruits and flowers, from the stately palm to the brilliant balsams, with which it has pleased the Creator to clothe our island.

INDIAN TIMBERS FOR TEA BOXES AND OTHER PURPOSES.

Mr. S. E. Peal, the wellknown Indian tea-planter, has commenced a series of articles in the *Indian Tea Gazette*, of which the following is the first. Although Mr. Peal has not in this preliminary article arrived at the class of woods suited for tea-boxes, yet our readers will be interested in what he says about the best timbers for general purposes, the list being headed by the valuable *sal*, next to teak, we suppose, the most valuable of Indian timbers. Jak holds the second place in Mr. Peal's list, while ironwood comes third, as suitable for posts and outside work generally. *Lagerstræmia regina* becomes a large and valuable timber tree in Northern India, while in Ceylon it is rare as an ornamental tree. Have our foresters devoted any attention to it ? Mr. Peal's list, it will be observed, includes two varieties of sapus, while the golden-flowered *cassia fistula*, common in the Eastern Province jungles, takes rank amongst the most useful timbers. A forest of *Lagerstræmia* and *cassia fistula* would certainly be "a thing of beauty."

In classifying woods for practical purposes, we may omit their botanical relationships, and look on them solely in regard to their uses ; thus some woods may be specially suitable for special things, while others may be good for several.

Firstly, we may take those more suitable for outdoor work, and in doing so divide them into two groups,—those that are in the ground or under water, as posts of houses and bridges, and those for upper work.

For outdoor work, as posts, &c.

The list of woods suitable and reliable under this heading are comparatively few ; extreme hardness and weight also are not, as some might suppose, essential. The lasting qualities appear to be due more to chemical or organic structure, than to density, thus Saw, heart wood of old trees at least (*Accasia stipularis*), is both extremely lasting and extremely light, and like the Maiphak, (name so far unknown botanically) appears due to a resin among the fibres of the wood, and which also seems to protect them in some measure from the ravages of insects.

The woods best suited for outdoor posts, &c., are—

Sal,	Shorea robusta.
Jack,	Artocarpus integrifolius.
Nahor,	Mesua ferra ?
Ajar,	Lagerstœmia regina.
Gondserai.	
Koroi,	Accasia.
Gomari.	
Tita Sopa,	Michelia.
Korika Sopa,	,,
Uriam,	Audrachne trifolium.
Gahora.	
Toi angoli jamok.	
Sonaru,	Cassia fistula.
Amsia.	

No doubt a secondary list might be made up of such woods, as Moj, Maipak, Paroli, &c., but the above are more reliable as bridge posts, or house posts, most of which, while they often last well above, yet go between wind and water, or near the surface of the ground. It is seldom that a post decays to the very foot, say at 5 feet, below the surface, decay usually occurs within a foot of the surface each way—and may be due to the presence of air and moisture, both at the one spot, including some form of oxidation.

Of the foregoing trees undoubtedly Sal stands the highest (for we have no teak naturally), but it is not seen in Upper Assam, except in a few places, where it has been planted, but grows well. Like most of the harder woods it sinks in water ; at times the Sal grows to a large size, as 10 or 12 feet in girth, at 6 feet from the ground, where it is usual to measure it, unless there are large roots standing out like buttresses. A clear shaft also of 50 feet to the first branch is not uncommon, but timbers of such a size are seldom needed, and very difficult to deal with. It may not be out

of place here to say that trees should be rung, or have a large ring of bark and sap wood removed, near the ground, some months, or even years, before they are required. Failure to season the wood in this way often induces dry rot. It is also better to season the stem standing, and before it is felled and cut up, as it is then much less liable to warp.

This rule of ringing timbers applies to all those having so-called heart wood; with softer wood it is not always possible: there are some that actually seem to rot ere they can dry.

Most of the woods in the above list are cross in grain, and difficult to work, requiring all tools to be both strong and sharp; the Sopas being the easiest and straightest of grain.

Jack is seldom found, in the plains at least, very straight. It is usually more or less curved, and with large branches, comparatively low down, and if grown for timber, these should be removed when young. There are said to be 2 or 3 kinds of jack, but the difference in the woods is not very great. Jack is a good wood for the tables of rolling machines, being tolerably tough and dense.

It stands weathering out of doors better than many other woods on this list.

Nahor, if well grown, is a fine wood; at times it is seen 10 to 12 feet in girth, and straight clean shaft for 45 and 50 feet. As a rule in the plains the straighter ones are young, and the old ones more or less crooked. The forest if properly studied, often yields information of peculiar kind: thus the above gives a clue to the density of population compared to what we see now. These large old and crooked branching Nahors clearly indicate that when young, the country (now forest,) was then open. They are often along the sides of old bunds in dense forest, and evidently planted, and from the seed the surrounding Nahor forest has sprung up, and it is generally as straight as the old trees are the reverse. As a tree the Nahor is very ornamental: the young foliage out in March is a bright crimson, and the tree if in the open, a cone of foliage, and later in the year, about May, the blossoms out in profusion are like large white wild roses, often in bunches, and perfume the air all around. The immense bunch of stamens in each flower are a deep golden colour, and contrast beautifully with the large white petals. No wonder the tree was a favourite in old times. It was mainly on this account that it was planted about. As a wood Nahor is hard and cross; it is also fairly heavy, and the "heart" lasts well in the ground as posts, going for 16 to 20 years or so. For indoor and lighter work Nahor is a very second-rate wood, on account of being comparatively difficult to work: there are so many much better. Its main use is for posts, in tea estates at least, or where strength is needed.

Ajar (called in Cachar Jarul) has also a handsome purple blossom or spike of blossoms. It is at times a large tree, 8 and 9 feet in girth, and perhaps 40 to 50 in the shaft; and if in the open, is very handsome when in flower.

For lasting in the ground, or water, it has a reputation quite equal to Nahor; and the heart, if large, can be relied on for 12 or 14 years. The wood is rather lighter and more easily worked than Nahor, which it somewhat resembles, in other characters, of strength and toughness: it is a first-class useful wood.—S. E. P.

PLANTING IN THE HILL-COUNTRY OF CEYLON: GENERAL REPORT.

Kandy, 1st May 1883.

The weather keeps up wonderfully, and slight dribblet blossoms peep through the dark foliage of our luxuriant coffee! 'T is true and 't is a pity, crop again seems *most* disappointing: our hopes and fears are having a lively time of it this season on the *Kandy* side. *The* blossom of the season does not seem to have profited by fine weather, and the result I fear will be yet another *short* year. On many estates the wood, which has been making rapid growth lately, is too young to mature blossom for this season. It is nevertheless of a stronger nature and more of the "good old style" than I have noticed for some years. So let us take unto ourselves a fresh stock of hope, keep expenditure *down*, and our spirits *up*, and peradventure mortgagees may *bear with us* yet one more year. Haputale and Uva seem in luck once more. It does one's eyes good to see such fields of coffee. Crops are not doomed in those districts yet-a-while, judging by the appearance of the bushes, and the prices realized at home for brands like Kelburne, Wiharagala, Golconda, etc., turn the tables completely on former years. A whisper has it that B. & H.'s curing has touched up some of the "sleepy hollows" of our merchant princes and not before it was *badly* wanted.

What a grand thing for planters in this island that the price of rice continues so moderate. We may also thank our stars that "Ramasamy" is so amiably disposed and content to work four days a week, no doubt with an eye to his "pickings" in crop time *au revoir*.

TEA AND COFFEE.

As the Budget arrangements are to be discussed in the House of Commons next week, the tea trade, as is usual, canvass the prospects of a reduction in the duty. Owing to the great fall in the value of tea, that charge has become proportionately far greater than it used to be, and forms quite 50 per cent. on the average wholesale price, while on some perfectly sound, although common, Congous, which have been selling at as little as 4½d per lb., the duty is 125 per cent. of the wholesale value. By the time the tea reaches the public the burden is much greater, as the wholesale and retail trade have to be paid for collecting the revenue in infinite detail, and the Grocers of course reckon their percentage of profit on the retail price. In consequence of the increased proportionate burden upon tea, the trade certainly think they have a claim upon the Government's consideration as to the duty. At the present moment, however, there appears no prospect of the removal of this great obstacle, not only to the use of tea in this country, but to increased trade with India and China in tea and in our own produce. As the revenue will apparently not bear any considerable sacrifice, such as the removal of the tea duty.

It is singular that India not only excels China in tea, but produces far finer coffee than that grown in any other country. This may be partly due to the virgin soil upon which most of the southern Indian coffee is grown and to the climate, but the energy and ability of our planters also count much for in the result. The clearing of a tropical forest and its transference into a coffee garden are most arduous undertakings; and the English pioneers, leading solitary lives in fever-haunted jungles, have anything but an enviable time of it. Indeed, for several years, the planter's life in a new district is one of the most miserable that can be conceived. All the more credit is therefore due to those, who, under such difficulties, have brought Indian coffee into the very front rank. The planters also keep themselves informed of all that is going on. For instance, at the Madras Agri Horticultural show, held by Government on the 24th February last, samples of coffee from no less than forty-three estates in Mysore, Coorg, Wynaad, the Neilgherries and Travancore were exhibited. The prize medal was carried off by the "Cannons" Mysore coffee, which is so well known to the home trade.—*Produce Markets' Review.*

AN APPLE in perfect preservation, although ninety-six years old, is in possession of a getleman in Ulster County, Pennsylvania. As it rounded up from the blossom of the parent stem in the early summer of 1787 a bottle was drawn over it and attached to the branch, and after the apple had ripened the stem was severed and the bottle sealed tightly. It looks as fresh as when first plucked.—*Home paper.*

PAPER IN CINCHONA CULTURE.—In Ceylon, where much attention has of late been given to Cinchona culture, stout brown paper has been found an effectual protection for the trees after they have been "shaved," or had their bark removed. The paper will not, however, stand the south-west monsoon, "We suggested," says the *Tropical Agriculturist*, "that brown paper might answer if the outside was tarred, and we are also going to try what the stationers call 'duck back paper,' but that is expensive." If the planters find paper answer the purpose, there will soon be a good market for a tough waterproof wrapping in that region.—*Stationery Trades Journal.*

A NEW SUBSTITUTE FOR QUININE.—Messrs. Parke, Davis & Co. bring before the notice of the medical profession, by their *Therapeutic Gazette*, a new herb, brought from the Sierra Nevadas, where it is said to have long enjoyed a local fame, known under the name of "Sierra Salvia," or Mountain Sage. Botanically it is the *Artemisia frigida*. Messrs. Parke, Davis & Co. are having its claims tested. Dr. Comstock, of Silver Cliff, Colorado, who introduces the plant to the profession, declares that in his experience "the intermittent, remittent, and congestive forms of fever yield to this herb much more readily than to quinine, and with infinitely less disturbance the to system."

MULBERRY CULTIVATION IN INDIA.—At a meeting of the Government of Madras, Revenue department, on 28th March, a letter was read from T. W. Holderness, Esq., C. S., Officiating Under-Secretary to the Government of India, Revenue and Agricultural Department (Fibres and Silk), to the Secretary to the Government of Madras, dated Calcutta, 16th March 1883, forwarding for information and communication to the Director, Department of Agriculture, copy of a letter, of the 1st February last, from the Superintendent, Botanical Gardens, Saharanpur, on the subject of the cultivation of the mulberry tree. In this letter the varieties of mulberry under cultivation at Saharanpur are detailed, and the mode of cultivation is described.

AN ENEMY OF THE CINCHONA.—A planter writes:—"I forward you 9 'poochies' which I found on 8 months' ledger plants, in my new clearing. On careful examination, I found that they do not seem to attack the succirubra, hybrid, officinalis or calisaya plants. The leaves sent along with them are of 3 days' destruction off one tree. I do not know if they are one of the enemies of cinchona, so should like to know through the medium of your columns what remedy will the best to keep them off and save my ledgers. The tree had from 50 to 60 leaves, out of which the 4 sent are the remnants. Out of all the ledgers affected, I can find no other 'poochies' but these." Our entomological referee reports as follows :—"A weevil of a greyish-brown colour, Whole of body and legs covered with scales having a slightly metallic lustre. Largest specimen 6-10ths of an inch. Smallest 4-10ths of an inch. Should be collected and destroyed, which is considered the only remedy."

THE QUESTION OF MANURES is at present exciting a good deal of attention in France; ought they to be mineral, though erroneously termed chemical, manures: or organic, which comprize the refuse of animal and vegetable products? Professor Baron, of Alfort College, leans to the latter class, of which farmyard manure is the type, while Professor Georges Ville, as strongly advocates inorganic fertilizers. Farmyard manure ameliorates the soil; by the slowness of its decomposition it imparts from time to time the doses of nutrition required by the plant. But the pulverized mineral phosphate of lime, sulphate of ammonia, nitrate of limes, the salts of potash, &c., also augment the yield of crops. There is nothing definite to prescribe: the layer of arable soil requires a mixture of various substances, which are decomposed by certain forces, and transformed into food for plants. How the latter feed themselves, science cannot yet say; cannot state how starch, sugar, albumen, and cellulose are produced in nearly all plants: how immediate principles are produced in certain plants; nicotine in tobacco; essential oils in odoriferous plants; quinine in cinchona; citric acid in lemons, malic acid in apples and pears. Soils and plants require fertilizers, differing in kind and amount; exclude none, but ever judiciously select. Some crops are gluttonous for phosphoric acid, others are dainty for nitrogen; spring is the season for employing complementary manures of a soluble nature, while autumn is better for such as decompose slowly.—*Madras Mail.*

WEEVIL IN WHEAT.—The *Civil and Military Gazette* in the course of a very able article, showing how seriously its undrest and dirty condition places Indian wheat at a disadvantage when compared with American, goes on to notice another great evil thus:—A former Lieutenant-Governor took great interest in this trade; which he, with an almost prophetic eye, foresaw would one day arise. At his suggestion, many experiments were conducted with a view to discovering an effectual and practical means of destroying weevils and grain moths—the curses of Indian grain. A perfectly simple method for their destruction was discovered; but whether the application of the method would be feasible under all circumstances, or whether it would affect the market value of the grain, we are not prepared to state. The losses from weevil are so enormous as to defy calculation. One pair of weevils have been known to reproduce 6,045 of their kind in five months; and the birthplace of each of these weevils is a grain of corn, which the inmate does not vacate whilst there is still anything to devour. The systematic destruction of such pests is worthy the attention of any Government.

FODDER RESERVES.—In one district of India alone, half the cattle, or 250,000 head, died from starvation in 1877. Disasters of this sort have resulted from an increase of the population, which advances further and further into the jungle, bringing into cultivation cultivable waste land, which formerly served the purposes of village grazing grounds. Precisely the same encroachments occur in Europe from the same cause—that of increasing numbers. But owing to the greater constancy of the weather in temperate climates, the effects there are not serious. In such places, compensation for the lost grazing ground is found in the increase of cultivated fodder crops, upon which reliance can be placed from year to year. But in India, things are different. In unirrigated tracts—that is, over a very large part of the country—if droughts occur, and we know that they do so periodically, the fodder crops wither and die, and the cattle, having no longer any jungle to which to turn, perish miserably. The Government of India is therefore setting itself to work to remedy this state of things, by protecting and enclosing forest grazing lands. This will serve a double purpose The long-rooted grasses deriving a supply of moisture from below, and the shallow grasses protected by shade above, will then furnish food for cattle, while the the bushes and smaller trees will reproduce themselves by seeding, and provide fuel. Something has already been done in this way in Ajmere; and the results, after five years only, are said to be most encouraging, the appearance of the hills and countryside being quite altered. Averse as the villagers must be at the outset to a proceeding which encloses even a portion of their grazing lands for a time, they come to see the advantages of it when drought is upon them, and will, no doubt, before many years have passed, be allies, instead of opponents, of a measure designed solely for their benefit. In Ajmere, side by side lie protected fodder reserves and unprotected jungle, and the difference is most striking, though the enclosures have existed so short a time. "The first are covered with an almost impenetrable thicket, chiefly composed of shoots edible by cattle. The second are practically devoid of all vegetation, and appear to be mere heaps of rock and stone."—*Indigo Planters' Gazette.*

Correspondence.

To the Editor of the "Ceylon Observer."

DIVI-DIVI CULTIVATION.

Heneratgoda, 20th April 1883.

SIR,—I beg to annex extract of a letter just received From an experienced divi-divi planter in India. Trusting it will be useful to the majority of your readers, yours faithfully, J. P. WILLIAM.

(Extract referred to.)

"I am in receipt of your letter regarding the cultivation of 'divi-divi.' There are so many applications for the seed of this tree, and each application requiring full instructions as to the proper method of its cultivation I find it difficult to keep pace with the demand, and as it has been so strongly recommended by the Governor-General of India, I think the least the Government could have done would have been to publish a pamphlet explanatory of the modes to be adopted.

"*The beginning* is of the utmost importance as with a false start the ending will sure to be disastrous, and I feel very sure from information I have received that many of the speculators in this enterprize will look on their speculations with dismay. The first thing to be very cautious about is the selection of the seeds which should come from mature trees and mature trees alone. The seeds which I have used have been taken from trees upwards of twenty-five years of age and upwards of thirty feet in height, the result being that the young trees in the plantation from six to seven years of age show themselves in such fine condition and have given such bumper crops for the year 1882-83.

"Now about the preservation of these delicate seeds: they must on no account be exposed to the atmosphere until the nurseries are ready to receive them. Kept in hermetically sealed pods they are perfectly safe, but in sending them upcountry to save extra charge for carriage I send them in clean dry bottles well corked and well dammered to protect them from the atmosphere. In sowing them in the nursery little holes not more than one quarter of an inch deep and seven inches apart have been universally followed by me. They are not sown deeper than a quarter of an inch, as the sun would not have the necessary power to force their germination and in point of fact, when I have found some of the seeds fail I have had them dug up half-inch and three-quarters of an inch deep and have usually found that they had germinated at that depth, but had been smothered by the extra moisture, and the little seedlings which are of so delicate a character, could not penetrate the extra soil above them. The reason for setting them seven inches apart is that when ready for transplantation they can be cut out with a ball of loam without injury to the taproots, which will be in about six months after sowing, when they will be from two to three feet in height.

"The plan adopted by me in planting out was to have pits dug three feet square and at least two feet deep and twenty-two feet apart; the pits were then filled in with a little manure and sand mixed with the loam. Channels are then cut from pit to pit, so that water discharged at the higher level would, as a natural circumstance, run down to the lower. This watering process I have found to be necessary during two or three of the hottest months in the year. Plants under unusually favourable circumstances have given small crops in the second year; they nearly all blossom after the third year. The produce, however, would not besuitable for propagation, but somewhat suitable in the industries, dyeing, tanning and making ink.

"An ounce of the seed, if properly attended to at the beginning should yield on an average 1,250 seedlings: at least, that has been my average. For the first two years a little attention should be given in cutting away the side or spring branches, in the third year the lower branches especially the weak ones should be pruned away and the plant made to assume as much the appearance of a tree as possible. In some instances this has not been accomplished under four years.

"On the subject of preserving them from the atmosphere until ready to be sown there is a very curious fact which I have omitted to mention. In each seed there is the spawn of a maggot which begins his boring explorations after 36 hours' exposure to the air. In three days the maggot will be found to emerge at the apex of the seed totally destroying the germ which contains a good deal of saccharine matter and hence it is useless labour to sow such seeds although I hear it is commonly done throughout southern India. A native young gentleman who has been working with me as accountant and auditor for the last 15 months has taken great interest in the cultivation of the "divi-divi," and, if sufficient inducement offers, he says he is willing to proceed to Ceylon and superintend as many plantations as may be within an easy distance.

"In no case must the bottle be opened until the nursery is ready to receive the seeds, as I have known the borer to start when seeds have been exposed barely one hour.

"I may mention that 'divi-divi' will not thrive at a higher altitude than 2,000 feet."

MESSRS. CALVERT & CO. ON CARBOLIC ACID.

SIR,—In your paper of Feb. 23rd we note a statement* that carbolic acid exposed to the open air *does not evaporate*. This cannot be considered an accurate opinion, as we could tender numerous *proofs* to the contrary!

In a paper "On the treatment of pulmonary disease," read before the Medical Society of London on the 12th inst., we find it stated that "carbolic acid has the singular property of volatilising in exactly the same proportion as the water with which it is mixed (*i. e. dissolved*); and thus it is the most suitable for all antiseptic methods of treatment."

Regarding its possible *utility* as a remedy for the coffee leaf-disease we cannot venture an opinion, and it is a matter for simple experiment, but of its good effect in vapor on the bacilli or germs developed by fevers, feet and mouth disease, epizooty, consumption, and other kindred ailments there can now be *no doubt*, because the fact is generally admitted by medical and scientific men who have carefully investigated the question and can vouch for the results of their experiments. Professor Koch's remarks on carbolic acid being *inert* when dissolved in water or oil are so opposed to an enormous mass of scientific evidence by eminent men (including Professors Lister, Tyndall, Crookes, Nussbaum and Rays Lankester) that we may reasonably assume Professors Koch to be at fault if he has been correctly reported. Anyone can test the question by adding carbolic acid to a watery solution of some putrescible matter in the ratio of 1 part acid (also known as phenol) to 500 parts of the solution and comparing it, after some weeks, with part of a similar solution *not* treated with carbolic acid (phenol).

It is clearly proved that all so-called micrococci or bacilli are themselves developed from spores, or eggs, which have so tenacious a vitality that they cannot be destroyed by prolonged boiling or even by strong solutions of any antiseptic; but these spores when gradually developed are readily killed in the first stage of their life, as bacilli or microbes, when encompassed by carbolic solutions or vapor.

In view of the facts regarding these spores, as expounded by Prof. Tyndall, it is easy to see why a continuous disinfection for varying periods becomes needful to ensure complete destruction of spore life, which can only be attacked effectively after passing into the bacilli or *active* stage.

The subject of this letter, being of very general importance, will, we trust, justify its insertion in your paper.—Yours truly, F. C. CALVERT & Co.

[The subject is certainly a very interesting one, and for ourselves we can say that we cannot understand any person with a nasal organ doubting the vaporiz-

* By Mr. Geo. Wall.—ED.

ation of carbolic acid. Its disinfectant and medicauses too, are well established, and we do not feel that this substance ought to be in any way discredited because, used in the open air in saucers placed at intervals over a field, it has not answered the sanguine expectations of men like Messrs. Schrottky and Storck. Messrs. Calvert & Co. enclose the following paragraph in their letter :—"A French chemist claims to have discovered a method of overcoming the danger threatening vineyards from the ravages of the phylloxera. His process is to inoculate the vine with the phenol [Phenol is carbolic acid.—F. C. C. & Co.] poison. The phylloxera do not attack plants thus treated, and are extirpated for want of food. The vines are in no way injured by the inoculation process.—*Lucknow Express*, Feb. 3rd." We believe Mr. Scrottky tried inoculation, but without success. Inoculation of the vine with a solution of phylloxera insects, and of the coffee trees with a solution of the fungus, would seem, from the analogy of Pasteur's experiments in the animal world, to offer more chances of success. Messrs. Calvert & Co. send also copies of printed certificates from medical and scientific men as to the disinfecting properties of carbolic acid in cases of smallpox, fever, &c., which are familiar to most of our readers. We think it highly probable that the vapour of carbolic acid would be potent to the extermination of leaf fungus on coffee trees in a conservatory. Fields of hundreds of acres in the open air seem beyond the power of any remedial agent except that of the great healer, time.—ED]

ANDROPOGON MURICATUM (CUSCUS GRASS, ENGLISH).

DEAR SIR,—Kindly let me know per your columns if there is any demand for cuscus root and what will be the price per cwt. of root. These are used for making fans &c., and there is little demand for medical uses in this country. The Tamil name is vatti-vam. This grass is growing very splendidly on upcountry estates, the root is giving a good lavender smell, so why not they used for mattresses?—I remain, dear sir, yours obdtly., J. P. ABRAHAM.

[Perhaps some of your readers may answer Mr. Abraham as to the sweet-smelling roots, "Why not used for mattresses?" We fear they would be brittle and perishable. Kuskus tatties are largely used in India in the hot weather, and we do not see why, to some extent, they should not be used here. What has Mr. Sumps to say? For tats, fans, &c., made of kuskus, we should think there would be a demand in Australia. ED.]

SHAND'S PATENT STEAM DRIER.

Colombo, 23rd April 1883.

DEAR SIR,—Will you allow me to point out to the writer of the letter in your Saturday's issue on tea drying by steam that the machine referred to is an infringement of the patent granted to me by Government in 1879. In using my drier there is no possibility of an explosion, as the steam is allowed to escape as fast as it is generated : in fact there is no more danger in boiling water in it than there is in boiling in an ordinary tea kettle. To thoroughly dry tea a temperature of from 213 to 280 degrees is not required.

Any person desirous of ascertaining this can satisfy himself without even investing in one of my models, by putting a wide-mouthed chatty of water on the fire, and placing over it one of those large earthenware rice bowls : the surface will heat 170 degrees which is hot enough to dry thoroughly anything.—Yours truly, C. SHAND.

TEA-PLUCKING.

Nawalapitiya, 28th April 1883.

DEAR MR. EDITOR,—Your correspondent "A. B. C."'s notions of tea-plucking are apparently very crude and fairly well represented by his signature. Does he imagine that our "teatotams" are stripped of *all* their young leaf once in, say, 8 to 10 days? The growth of flush (allow me to enlighten him) is gradual. Our "Hindu brethren" are therefore instructed to pluck only that flush which has attained a given size. An eight daily round secures all leaf from hardening, viz. from growing past the flush period, and also ensures the whole produce—in leaf—of the best quality, from your estate.

If the flush is small "Ramasamy and his satellites" have only to get over more ground to obtain their "kanak" for NUMONA THARMA DURAI.

Of course the tree makes an effort against nature from the very first pruning, and plucking is only a miniature pruning.—N. T. D.

QUEENSLAND AND NEW GUINEA.—From an article in the *Straits Times* on the recent annexation, we quote the following paragraph :—It will be interesting to read the remarks of the Continental press with reference to this step with New Guinea : although Queensland enjoys self-legislative powers, yet in matters of Imperial interest the sanction of the Home Government has to be obtained, especially before any alteration of her boundaries can be made, as in the case only a year or two ago when she "amended" and extended her maritime boundary to within three miles of the New Guinea Coast ; this included the whole of Torres Straits now so fast becoming a highway for vessels ; indeed, Colonel Scratchley, R.E., on his recent Colonial tour of inspection, recommended a schemeof defence commanding the main passage, and the Imperial Government already allow £500 per annum towards the maintenance of the establishment at Thursday Island.

CINCOHNA : YARROW LEDGERS' ANALYSES.—We learn that the last mail brought out the results of further analyses of Yarrow ledger bark from 5½ years old trees by Dr. Paul of London, and we feel, sure our readers will agree with us that they are simply *splendid*, especially No. 5—*14·50* per cent of crystallised sulphate. The superintendent of Yarrow has sent down 100 lb. of ledger bark from trees thinned out and, as a test of what it will fetch in the local market, Messrs. Somerville & Co. have been instructed to sell it on Mr. Symons' *average* analyses of 5·77 per stem and 4·17 per branch bark. The result of sale will be duly reported. With Dr. Trimen's report and such encouraging results as we are now able to place before the public there should be no hesitation about extending the cultivation of ledgers. The analyses are as follows :—

ANALYSES OF YARROW LEDGER BARK FROM 5½ YEAR OLD TREES.

Number of Samples. No.	Crystalized Sulphate of Quinine.	Quinidine.	Cinchonidine
1	12·30	Nil	Nil
2	7·94	„	„
3	11·82	„	·93
4	11·90	„	·75
5	14·50	„	·20
6	12·50	„	0
7	6·10	·83	·40
8	8·50	0	·75
9	10·40	0	0
10	11·40	·15	·10
Samples 10	107·36		

10·73= average of 10 samples.

COLONIAL GUM COLLECTING.

Mr. Thomas Kirk, F.L.S., a New Zealand botanist of note, recommends to the notice of Colonists in that island the shrub *Astragalus tragacantha*, which grows freely in Asia Minor, Armenia, and Persia, and in Northern Syria, at an altitude of 5,000 feet, and from whose sap the useful gum known as Gum Tragacanth, sometimes called Gum Dragon, is derived. Although probably not so valuable a product as gum arabic, not being applicable to so many purposes, this gum nevertheless forms an important item in the commerce of the Levant, the town of Smyrna alone exporting annually more than 70,000*l*. worth. From the similarity in climate between the Colony and the natural habitat of the plant, Mr. Kirk is convinced that the culture of the plant might very successfully and very profitably be taken up in New Zealand, where the collection of its gum would soon rank as an important item among other pursuits of a similar nature. Another gummiferous plant, which has lately attracted much attention in Australia, and which might probable be introduced into other Colonies, is the *Eucalyptus resinifera*, usually called the Red-gum tree, which yields a volatile, aromatic gum from both its leaves and its trunk. This gum is stated by experts to be almost identical with the better-known Gum Kino, a valuable drug as well as a useful dye, obtained principally from the East Indies, where it is boiled out of the bruised twigs of the *Nauclea gambir*, the decoction being afterwards evaporated to the density of an ordinary extract. When the bark of the Red-gum tree is wounded in a proper manner as much as sixty gallons of sap, equal to five hundred pounds' weight of the drug, may flow from a single tree. Another candidate for tropical Colonial culture is the great conifer which yields Gum dammar, long a specialty of the Moluccas. The celebrated Kauri pine of New Zealand (*Dammara australis*) is a member of the same family, with the advantage that, though it grows in a temperate climate, it yields a valuable gum of a similar nature. The yield of sap in the species generally is indeed most abundant—so profuse, indeed, that, in some of the gigantic Moluccas specimens, it exudes spontaneously. The Kauri gum of Auckland, of which such considerable quantities are shipped, is the hardened and semi-fossilised exudation of ancient Kauri trees which ages ago ceased to exist, and whose imperishable product is found below the surface of the ground. This unique industry is, of course dependent on the exhaustion of the stock of buried gum, and it ought to be supplemented by the careful extraction of gum from the living trees. Properly carried out, this extraction of gum may be a perennial source of profit, while, on the other hand, the improper tapping of the trees may result—as it has too often already—in the destruction of the source of supply.—*Colonies and India.*

"FUNGUS—A CAUSE OR A CONSEQUENCE OF DISEASE."

A writer in the *Garden* who is a skilled horticulturist, and who evidently leans to the theory that fungi are commonly a consequence of disease, whilst admitting that both cultivators and fungologists are pretty well agreed that the fungus (peronospera) is the cause of the rot in potatoes, suggests the possibility of their conclusions having been too hastily arrived at. In hot and dry seasons, he says, the fungus (left from the preceding season) is there, but is unable to make any progress. When the conditions alter, and wet and uncongenial weather sets in, the fungus is developed, but not until after the potato has suffered from the altered conditions. In reference to the curl or blister in peaches he says :—"There has at times been some discussion regarding a disease in peaches called 'blister,' which fungologists have declared was also caused by a fungus, because they found the fungus present in the injured leaves; but no cultivator believes it, because they know that under conditions which they could provide at pleasure they could defy the fungologist to produce 'blister,' even if he were to dust the leaves of the trees with the spores of the fungus 20 times a day. Practical men call that a cause which by preventing they can cure or arrest the disease, and this, it seems to me, is the point so-called 'scientific men' should concern themselves about instead of dealing with secondary causes, which is, perhaps, all that they are able to see or have any knowledge of. If it were proved that fungi always preceded disease in animal and vegetable bodies, it would settle the matter, but that is just where the difficulty lies, for it is perfectly well known that many kinds of fungi follow decomposition or decay." Instances are cited of the annual production of "toadstools" in ground containing portions of the rotten wood of felled trees, and which appear in no other part of the grounds than in the hollows caused by the subsidence of the soil employed to fill up the holes where the trees grew. Of the vine mildew, which is to Australians by far the most interesting subject, he writes :—"You may produce it almost with certainty on vines if you lower the temperature of the vinery when growth is active, so as to produce a cold, stagnant atmosphere, and it will of course destroy the crop and the foliage, but the very conditions that produce the mildew would do the same if prolonged sufficiently. Cultivators and their suggestions have, until lately, been rather ignored by scientific investigators, but the latter, having exhausted their specifics, are now appealing to the former for assistance. When many years ago the farmer said the potato disease was caused by the wet, and could only be prevented or alleviated by contending with that evil by means of drainage, choice of soils, or protective measures for that end, he said all that could be said, and suggested the only preventive measures that have yet been found in any degree efficacious, and the same may be said of peach blister and other things of a similar character."—*Australasian.*

THE ACCLIMATIZATION SOCIETY OF QUEENSLAND

is the Society of which Mr. Bernays has been the life and soul, and which has achieved such large success. From one of its annual reports we quote:—

"The progress of plant acclimatisation in new countries—slow, and beset with obstacles at all times—appears more so from the difficulty of ascertaining results over so wide an area of operations as that occupied by the society. Attempts have been made at intervals, by addressing circulars to the society's constituents within the colony, to learn what success has attended their efforts at cultivating the plants sent to them; but the information obtained in this way has been, with very few exceptions, imperfect and unsatisfactory. It was therefore deemed advisable that the principal plantations and gardens of the older settlements along the line of coast northwards should be visited; and the vice-president (Mr. L. A. Bernays) was accordingly deputed to undertake this interesting and important task. The result of this gentleman's investigation is embodied in a report to the Minister for Lands; the Government approving of the project and having given it their support by sharing the expense of carrying it out.

"Since Mr. Bernays' return, and upon his advice, very large numbers of plants, the ultimate success of which is least assured, such as the mangosteen and the bread fruit, together with others which afford good ground for hope, such as the nutmeg, the cocoa, pepper, &c., &c., have been passed away among our northern constituents, the rainy season occurring opportunely and the stocks being ample for the purpose. Increased vigor has been imported into the introduction or propagation of those plants, from which the best results are looked for, and measures have been adopted to introduce in quantity others which have yet to be tried, but which, from their similarity of habit or other analogy to some already in cultivation, may be expected to find a home in Queensland soil.

"The relations of correspondence with foreign parts have this year been materially extended, communication having been opened with the following places, namely:—Bahia, Buenos Ayres, Canary Islands, Cuba, Chili, Cochin China, Ecuador, Florida, Florence, Greece, Guatemala, Guadaloupe, Guiana (French and British), Georgia, Hungary, Hayti, Jamaica, Lisbon, Martinique, Mexico, Manila, New Grenada, Pondichery, Peru, Palermo, Reunion, Rome, Turkey, Turin, Tahiti, Uruguay, Venezuela, and Zanzibar. From not a few of these communications results have already flowed, while in the case of others the overtures of the Society have been met in a friendly and promising spirit.

"A transaction likely to be attended with valuable results has been carried out in the importation, through the medium of Mr. John Bramston, of the Colonial Office, of a large quantity of seed of the "guango" of Jamaica (Pithecolobium Saman). The rapid growth of this tree, its elegant umbrageous character and adaptability to arid country, and its value as a fodder producer, are all qualifications pointing to its usefulness for cultivation on a large scale in Queensland. The seed has been widely distributed, and, as the receipients have been recommended to sow it where they intend the trees to grow permanently, it is hoped that in a very few years the guango may be found thriving wherever there is settlement and the climate proves suitable.

"The expotation of indigenous seeds to foreign constituents is largely on the increase. Difficulty is sometimes found in obtaining sufficient supplies from trustworthy sources; but intelligent collectors are not so rare as they used to be. As the processes of preparing, packing and transmitting seeds so as to preserve their vitality are better understood, seeds become to a larger extent the subjects of exchange, in places of plants, in all cases in which propagation of exact species by seed is practicable. By this means the lessening of risk and cost of exchanges, and the proportionate increase of material upon which to work, is very considerable.

"The subject of importing game and song birds has, at the instigation of Mr. W. Senior, specially engaged the attention of the council, and a good deal of useful information on the subject has been got together. The ordinary revenue of the society being, however, inadequate to bear the expense of transactions of this character, and the juncture not being considered favourable for the formation of a fund for the purpose by special subscriptions, the matter has been allowed to remain in abeyance for more prosperous time."—*Brisbane Courier.* [Looking at such a report as this, we may well wish that the scope of our Botanical Gardens were widened so as to include the introduction of useful animals and fishes. We want in truth a Ceylon Acclimatization Society.—ED.]

HARVESTING IN CEYLON AND INDIA—AND IN EUROPE AND AMERICA.

The recent harvest suggests many points of comparison with the same operation in other lands. In England and America grain is now largely cut by horse-power or steam. A row of sharp traingular two-edged knives is fastened to a bar giving the appearance of great teeth of a saw. This bar moves swiftly back and forth through a slit in a row of solid teeth. The sharp teeth passing through the solid teeth, cut off all the stalks of grain that come between. This double row of teeth, 4 to 8 feet long, extends from one side of the machine near the surface of the ground, and when the machine is drawn by the horses, it cuts all the grain for a width of 4 to 8 feet at the side. When grass is cut to be dried for hay it is allowed to fall as cut. In reaping grain a platform is attached on which the grain is gathered in straight bundles for binding. Sometimes the men who bind ride, and in some machines more recently invented, the grain is bound up with cords or wires by the machine itself With one of these, one man can cut and bind as much grain in a day as fifty men with sickles. But irrigation will need to be under better control in Jaffna before "reapers" can be advantageously used. Most of the fields are too small, and often, when cutting the grain, the ground is so soft that machines would sink in and be impeded. Fields 20 rods square might admit reapers if the ground were firm. The "cradle" might be used with advantage. This consists of a scythe or knife-blade about 3 ft. long and slightly curved, attached at an angle to a long handle. Parallel to the scythe and at equal distances above it are 4 or 5 fingers, or smooth pointed rods of light *tough* wood, of the same length as the scythe. These are attached by light framework and give the name to the instrument. The reaper swings this craddle before him cutting forward about one foot at each stroke in a path, called swath, 5 or 6 feet wide. The grain is caught by the wooden fingers and laid down even and smooth at one side, as the cradle swings back for a new stroke. With this, one man can cut as much as 3 or 4 men with sickles. The cradle is not easily used when the grain is fallen down.

Threshing is very generally done by machinery. The motive power is furnished by one or two horses walking on an inclined plane. This causes a cylinder to revolve rapidly, and teeth in the surface of the cylinder meeting other fixed teeth tear the straw to pieces and allow the grain to fall into a fan which cleans it, and empties it into bags. In California and Australia the thresher is sometimes one with the reaper, and the same machine cuts the grain cleans it, and puts it in bags. It might be profitable to have a horse-power for sawing wood at all seasons, and in harvest time attach apparatus for thseshing, which would not be expensive. Then all the grain of a neighborhood could be threshed in a short time. For small amounts the flail is used. This is a club attached by thongs to a long handle. The club is called a swingel and swings around the handle striking hard and flat on the grain and straw. Any carpenter could make one.

Probably as long as the farmers have a drove of these wretched starveling stunted cattle they will find it cheaper to make use of them for threshing. But when they think that it only pays to keep good cattle, then the flail will be introduced and the more elaborate threshing machine. The flails would even now do better for the dry grains than those curved clubs used by some.

Machines enable one man to do the work of several. By their help nature is more thoroughly subdued, and man's wants better satisfied. He has time, opportunity, and means for hire pursuits, and can come nearer the ideal perfect man. But every blessing may be a curse, and if man's heart is not right, machinery oppresses the poor and brings innumerable evils.—*Jaffna Morning Star.*

NOTES AND GLEANINGS.

The following are quoted from the *Garden* (London), in which they appear under the heading "American Notes":—

CELERY CULTURE MADE EASY.—I believe I have learned the easiest way to grow a family supply of celery. We this year filled our hot-bed frame, 3 feet by 12 feet, with celery plants, setting them about 8 inches apart each way, making 60 plants in the frame. They have grown splendidly, and as fast as they grow we fill in with earth, and they blanch nicely. I believe that they would have done as well if planted closer, say 100 plants in the frame. The advantage is that they occupy but little space, are not much trouble to cultivate, and require much less water than if planted in the usual way, with the rows 6 feet or 8 feet apart, besides a much smaller quantity of earth answers for banking up for bleaching, and of course If one has not a hot-bed frame, he can set boards less labour round the edge of a bed in the garden, and manage in the same way. Boards 1 foot wide should be used, and very cheap refuse timber will answer for the purpose.—*New York Tribune.*

DRY SAND AS PACKING.—The citrus men of Los Angeles, Cal. have made a discovery of great value to Florida. Dry sand is the best packing for oranges and lemons. It must be quite dry and no paper must be used. The fruit must touch the sand. Experience warrants keeping for five months at least. The dry sand has absorbing power that apparently takes up all exudations subject to decomposition, the rind being very porous. Naturally the thoughtful mind suggests that, on the same principle, dry sand must have a similar preservative effect on other fruits, such as pears, plums, nectarines, apples, and other smooth skinned varieties.

CLASSIFICATION OF SOILS.—Professor Johnston classifies soils, says the *Massachusetts Ploughman*, according to their clayey or sandy proportions, thus:—First, pure clay, from which no sand can be washed. Second, strong clay or brick clay, which contains from 5 to 20 per cent of sand. Third, clay loam, which contains from 20 to 40 per cent of sand. Fourth, loam, which has from 40 to 70 per cent of sand. Fifth, sandy loam, which has from 70 to 90 per cent of sand. Sixth, light sand, which has less than 10 per cent of clay.

LABELS.—We think that the label problem is solved. Lead pencil upon zinc will endure for many years—nobody knows how long. Over three yeears ago we marked a zinc

label two inches long as follows:—"Ulmus gras. Written with lead pencil Aug. 20, 1879." On the other side was written:—"President Gale's suggestion." President M. P. Wilder has since told the readers of the *Rural New Yorker* that he has used these zinc labels written upon with common lead pencil for many years. When first letters are written they so very indistinctly—just as if written upon glass; but in a few days they grow more distinct, and finally show as plainly as if upon painted wood. Copper wire alone should be used, for the reason that iron wire soon rusts, and the rust is washed over the zinc. This label is so far free from objections that we are now using if for all of our plants as the old wood labels wear out or the marking becomes indistinct.

EVAPORATING FRUITS ON A SMALL SCALE.—Fruit raisers who have a limited supply of fruit often wish to know of the facilities for doing the work of drying with their own hands without much outlay. We lately examined the work of a neighbour who performed all himself. He uses the American dryer, costing 75 dollars (formerly 40 dollars), which will dry twelve bushels of apples in a day, although much of his fruit is so wormy that he can cut only nine bushels. A hundred pounds of coal does the evaporating for twelve hours. Four hours are required to complete the process, or four bushels at a time. A bushel will make five pounds of evaporated fruit. Wormy and defective apples will give only four pounds. They are pared, cored, and sliced by machinery. The entire cost of dying is three cents per pound of dried fruit.—*Australasian.*

SUGAR.

The following table (taken from the *Journal des Fabricants de Sucre*) shews the average yield of Sugar from the Beetroot worked each season in the German Empire (or Zollverein):—

1840-41	5·88	1850-51	7·25	1860-61	8·62	1870-71	7·62
1841-42	6·13	1851-52	6·90	1861-62	7·94	1871-72	8·28
1842-43	6·25	1852-53	7·81	1862-63	7·52	1872-73	8·26
1843-44	6·58	1853-54	7·70	1863-64	7·58	1873-74	8·25
1844-45	6·67	1854-55	8·20	1864-65	8·20	1874-75	9·30
1845-46	6·80	1855-56	8·00	1865-66	8·55	1875-76	8·60
1846-47	7·14	1856-57	7·52	1866-67	7·94	1876-77	8·15
1847-48	7·00	1857-58	8·33	1867-68	8·13	1877-78	9·24
1848-49	7·25	1858-59	7·87	1868-69	8·33	1878-79	9·21
1849-50	7·35	1859-60	8·47	1869-70	8·33	1879-80	8·52
						1880-81	8·79
						1881-82	9·56

This is truly a most remarkable record of the progress attainable with patient science and skill. During the same period almost complete stagnation has reigned in our West Indian Colonies, where, instead of improving the strength of their plant year by year, and extracting every atom of saccharine, as the Germans do with the Beet, the Cane rather deteriorates than improves, and the Planters are contended with extracting one-third of the Sugar in the Cane in a semi-liquid state and one-sixth more as molasses. The resulting badly-made Sugar loses 10 to 15 per cent on the voyage to England, and then has to be sold 5s. to 10s. below the price of properly-made parcels. It must be remembered, also, that up to eight years ago there was no bounty on German exports, as the average yield only corresponded with that anticipated by Government. By far the greater part of the progress made was therefore aided by no extraneous causes, and even now the bounties can only be obtained by the utmost skill in manufacture. If the German bounties continue and increase for a few more seasons, their operation will compel reforms in the West Indies which nothing else can. The West Indian Planters, after throwing away two-thirds of the money they might get from their land, have hitherto been too prosperous to care to change, but when they are really pinched, when the old wasteful system no longer pays on a small scale, when estates are amalgamated, and modern machinery set up—then, sooner or later, a period of almost unheard-of prosperity would set in, and the Cane would at last being to compete with the Beet, with a tropical climate and 18 per cent of saccharine in its favour. To aid this result, there is ample room for half a dozen West Indian Committees, the more so as the one at home occupies so much time in the impossible task of getting foreign bounties of 3s. per cwt. removed, at a time when a large portion of its constituents are year by year sacrificing, certainly, one-half of their possible net income. The produce of the islands is about 250,000 tons of Sugar a year, worth, at 18s. per cwt., £4,100,000, and 125,000 tons of Molasses (and Rum made from it), worth, at 8s. per cwt., £1,000,000; a total produce of £5,100,000. The same fields, with proper machinery, would yield 500,000 tons of Sugar, worth, at 25s. per cwt., £12,500,000, without counting offal in the shape of Molasses or Rum.

The following, from *Nature*, mentions a new sweetener, of which the name will have to be shortened before it becomes a serious competitor with Sugar, even if the public were bold enough to put a coal-tar derivative into their Tea:—"A new substance, remarkable for its intense sweetness, being much sweeter than Cane Sugar, has been lately found by Dr. Fahlberg in the course of some investigations on coal-tar derivatives (*Journ. Frank. Inst.*). He designates it 'benzoic sulphinide,' or 'anhydrosulphamine benzoic acid.'"

The *American Grocer* states that the Hon. Geo. B. Loring, U. S. Commissioner of Agriculture, recently delivered a highly interesting address before the Mississippi Valley Cane Growers' Association at St. Louis. Speaking of the extent of the Sorghum industry in this country and its possibilities, Mr. Loring said:—"The fact that Sugar can be made from Sorghum has been proved. That it can be profitably made Professors Weber and Scoville have demonstrated, and have so declared to this association with their figures before them. That there is a market for the product, no man doubts. Whether it is a universal crop or not, time and experience alone can prove. Who can say, as yet, that this crop will take its place among the special crops of our extreme Northern and Eastern States, or will occupy the place now filled by the Sugar Cane of the South? Nor is this important. Like all other agricultural products, the profit of Sorghum depends on locality, soil, climate, and the commercial status of the cultivator as regards the ownership of his land; whether he possesses a plantation of thousands of acres or a small farm; whether he sets up his own Sugar mill and runs a Sugar plantation, or depends upon a neighbouring factory for his market of the crop from his few acres. We have a right to expect that it will find its place, as every other crop has done, and will be accepted in its proper sphere, either for the domestic supply of Molasses when convenient and economical, or for conversion into Sugar where circumstances are favourable. It took many years for the great cotton and woollen and iron industries to establish themselves and occupy the market, but their founders made their goods, found their market, and pocketed their profits. They worked with perseverance, economy, and great ingenuity and skill. You can follow their example."—*Produce Markets' Review.*

PSEUDO-GUTTA PERCHAS.

OR SUBSTANCES SUPPLEMENTARY TO GUTTA PERCHA.

Foremost amongst Pseudo-Guttas as we use the phrase, stands Balata Gum. It is obtained from the *Mimusops Balata* of Gærtner (*Nat. Ord. Sapotaceæ*) and is synoymous with the *Sapota Mulleri* of Bleekrod, the *Achras Balata* of Aublet, &c. It is found in Demerara, Berbice, British and French Guiana, Antilles, Jamaica, and Surinam. It has many vernacular names, amongst which may be mentioned, Balata, Paardenvleesch (Dutch—horse-flesh), bullet tree, &c.

One of the first writers on this substance was Professor Bleekrod, who communicated some information as to the plant and its product to the Society of Arts, in 1857. He, too, described the plant and named it *Sapota Mulleri*. In 1860 Mr. Walker communicated samples &c., received from Dr. Van Holst of Berbice, to the same society, and in 1864 Sir William Holmes also drew attention to the same subject. The tree is a large one with a trunk of about six feet in diameter, and furnishes a wood much liked for building purposes and of the colour of horse-flesh—hence the Dutch name. The bark is thick and rough, and the fruit is of the size of a coffee berry, sweet like a plum, and with a hard white kernel which yields a bitter oil.

The leaves are glossy, oval, and accuminated. The milk is

drunk by the natives, in cases of diarrhœa, and when diluted with water it is used as cow's milk. The trees grow in groups and in alluvial soil.

The "Balata" gum is of a character somewhat between caoutchouc and gutta percha, combining in some degree the elasticity of the one with the ductility of the other, freely softening and becoming plastic and easily moulded like gutta percha. What small parcels arrived in England met with a ready sale and were remarkably free from adulteration. But, unfortunately, through the difficulty of collection—the undertaking being so dangerous and unhealthy—the supply of this excellent article has fallen off. It is collected by making incisions in the bark about 7 feet from the ground, and a ring of clay placed round the tree to catch the milk as it exudes. The yield is said to be in profusion especially at the time of the full moon, and the operation can be repeated every two months in the rainy season. It takes six hours to bring about coalescence by simple atmospheric influence, but very quickly by boiling in water. A large tree is said to yield as much as 45lb. of "dry gum." The tree in every way is well worthy of a trial by acclimating it.

In India there are several plants whose products may be classed as Pseudo-Guttas. First and foremost of these we have the Pauchontee or Indian gutta tree, the *Bassia elliptica* of Dalzell, the *Isonandra acuminata* of Lindley, but now known as *Dichopsis elliptica*. It is found in the Wynaad, Coorg, Anamallay and Neilgherry Hills, Shokah Forest, Coehin, Sichar, and, according to General Cullen, "appears to be common in all the forest tracts at all within the influences of the south-west rains." This tree, which is now placed in the same genus as the true gutta percha, is a large one—from 80 to 100ft. high—and was first met with by Mr. Dalzell in North Canara, near the falls of Goirsuppah, in 1849. Since that date General Cullen and Dr. Cleghorn have used every exertion to bring the substance prominently forward, but without success. The gum is obtained by tapping, a pound and-a-half being obtained from one tree by five or six incisions, a large tree yielding as much as 20 to 40lb. of sap. Many experiments have been made with specimens of the raw milk, *i.e.*, milk simply dried by exposure to the atmosphere. The results of these experiments have shown that for telegraphic purposes it is wanting in some essential qualities, but it has been recommended as a sub-aqueous cement or glue. When dissolved in ordinary gutta percha solvents, it, after the evapofation of the solvent, remains some time soft and viscid, and partakes somewhat of the character of bird-lime. When cold, it is hard and brittle. Without wishing in the slightest degree to throw doubt or discredit on the many and valuable experiments made, we would suggest that good samples be collected and treated in the same manner as recommended for gutta percha. We have no doubt that many a parcel of what would otherwise be *good* gutta percha, is spoilt through not being well boiled *immediately* after collection from the tree. At present this is the only way in which we see there is a possibility of ascertaining whether this product can be utilized, and we have the more hope from the fact that the structural character has led the plant to be placed in the same genus as the true gutta percha—structural affinity agreeing so often to chemical affinity.

There are in India other nearly allied *Sapotaceæ* which deserve attention in order to ascertain whether any of them yield a milky juice likely to be of commercial use. Amongst the *Euphorbiaceæ* there are two plants worthy of notice. The *Euphorbia cattimandoo*, found in various parts of India, was first brought to notice by the Hon'ble W. Elliot, and a prize medal was awarded for this substance by the jurors of the 1851 Exhibition. This spiny Euphorb grows to the size of a shrub or small tree, and the milk flows out freely when a branch is cut. The natives use it as a cement to fasten knives in handles, &c. Under the influence of heat it becomes soft and viscid, and when dry very brttle. The *Euphorbia tirucalli*, the milk hedge or Indian tree spurge, is a succulent unarmed plant attaining a height of 20 feet, and its inspissated milk is used for various—chiefly medicinal—purposes, and has been recommended as a gutta percha substitute; but like gum *Euphorbium*, it has a very acrid character, and the collection is a very dangerous operation to the eyes.—*Indian Agriculturist.*

TEA IN AMERICA.—A petition has been presented to the United States Congress asking for the prohibition of the importation of adulterated teas from China and Japan, which are at present extensively sold. This, it is thought, will lead to increased attention being paid to Indian teas, which are well known to be pure and unadulterated.—*Indian Tea Gazette.*

THOMPSON'S "CHALLENGE" ROLLING-MACHINE.—Sir,—The special features of the "Challenge" are, *firstly*, free contact of the leaf throughout the roll with the outer air; cheapness (see advertisement); simplicity of mechanism; perfection of feed, discharge and pressure; minimum of power required. And I think I may here take the opportunity of informing your good self and the tea community generally that I have patented, and shall shortly have ready, two new inventions facilitating very greatly the other processes of tea manufacture, and greatly economising space required in the factory. They are:—A combined Dryer, Sorter, and Breaker, thus enabling the manufacturer to pack his tea right off, while the heat may be generated by any description of fuel. Also, patent withering trays so arranged as to occupy the actual minimum of space, while possessing every facility to fill and discharge the leaf.—Yours, &c., A. THOMPSON.—*Indian Tea Gazette.*

THE FUTURE GARDEN OF QUEENSLAND.—The works for uniting Herberton with Mourilyan Harbour, on the Pacific, are (says a Sydney paper) revealing unsuspected wonders on the coast range table-lands. The Palmerston party report that the elevated country intervening between the longitude of Herberton and the Pacific must one day become the garden of Queensland, so rich and deep is the chocolate-coloured soil, and so numerous and large are the rivers and creeks. The smallest ravines are reported to have water trickling down them. Broad sheets of water are also met with, falling over huge basaltic precipices. So dense is the scrub that some aboriginal tribes exist who have never seen open country. These are armed, not with spears, but with wooden swords, and followed the district Government exploring party for days in large mobs. The Johnstone River is large and deep, and empties itself into the Pacific ten miles north of Mourilyan Harbour, gold and tin being found in innumerable places along its banks. The flora of this region is reported to be of incredible luxuriance, and would well repay a visit by scientific men, as it possesses many shrubs and fruits heretofore undescribed.

PLUCKING TEA.—Many and varied are the ideas on plucking as on all other departments in tea gardens; some say pluck hard at first, others say let it run out well, but we imagine there must be a medium in this as in all things. We should first consider the number of flushes a bush is likely to give; some say 15, some say 8, some say 10, and so on, but we do not think we are far out in putting them at say from 11 to 12 during the season; and we will suppose that the first flush is allowed to grow to six leaves and then three are removed, leaving the 3 lower on the bush, or say 2 inches at the very least of succulent young wood which soon ripens into good red wood if the bush is vigorous. From the axils of those leaves left another flush springs up, which we may suppose is allowed to run to five leaves, when two or three are removed, and say an inch of wood remains, and for the remaining flushes allowing only one leaf to be left, or say ½ inch wood for the 11 flushes, we get, if plucked then, a growth of good wood of about inches for the season, which we think ample to prune upon the following season. We imagine, if planters' experience was taken upon the subject, the growth generally allowed is even greater than this, and we contend if the first flush is carefully removed and a good foundation laid, it is almost impossible to over-pluck a bush if in fairly good health. That there is nothing more easily done if the trees are not in vigorous health, we do not deny, but if at all in good health, it is an extremely difficult thing to do after the end of May, if carefully plucked up to that time. What we recommend therefore to our friends is not to be too eager in the commencement, else you kill the goose that lays the golden eggs, but to pluck very carefully for the first two months, and the result will not be disappointing.—*Indigo Planters' Gazette.*

THE BITTER PRINCIPLE OF HYMENODICTYON EXCELSUM.*

BY W. A. H. NAYLOR.

The interest attaching to the two species of *Hymenodictyon*, viz., *H. excelsum* and *H. obovatum*, is derived from the circumstance that they both yield a bitter bark which is in common use among the natives of India as a tonic. Surgeon-Major Dymock has remarked that the bark of *H. excelsum* is the more bitter of the two, and is therefore probably the more valuable, although he is not aware that either of the barks has been properly tested in European practice. As a remedy of repute it was invested with additional importance when it received a place among the non-official drugs of the Pharmacopœia of India for 1868. Referring to the species *H. excelsum* it is there stated that the "inner coat of the bark, according to Roxburgh, possesses the bitterness and astringency of cinchona. . . . The outer light spongy layer of the bark is comparatively tasteless. Considering the natural order to which the tree belongs and the sensible properties of its bark, it is not improbable that it may prove a valuable remedy. In all future inquiries into the subject of Indian antiperiodics this bark should be one of the first to which attention should be directed." The success which attended its use as a native febrifuge probably gave rise to the supposition that its medicinal properties were due to the presence of quinine. Consequently, in 1870, Mr Broughton who was at that time the Government Quinologist at the Ootocamund plantations, submitted to an examination the *fresh* bark of the tree. He found that the bitter taste was due to the existence of *æsculin*, and that the bark when dry was almost tasteless owing to its transformation into *æsculetin*, the decomposition having been induced by contact with decaying organic matter.—*Pharmaceutical Journal.*

JAPANESE SUGAR.

The sugar of Japan, says Consul-General Van Buren, is made from that species of the sorghum plant known as the Chinese sorghum. It grows luxuriantly in all the southern portions of the empire south of the 36th degree of north latitude. The whole product of the empire in 1878 was 64,297,580 pounds. Importation in 1878 was 67,434,805 pounds. For three or four hundred years the processes of granulating and refining sugars have been known and practiced. Sorghum is not grown, as with us, from the seed, but from cuttings. In September selected stalks are cut and buried in trenches a foot deep. Through the winter, from each joint of the stalks sprouts grow. In the spring these points are cut off and set out in rows 15 to 18 inches apart, and about the same distance from each other in the rows. The ground has previously been thoroughly dug up, and pulverized by a long-bladed mattock. The fertilizers used are ashes, fish, decomposed hay, straw and sea-weed, or night soil. The plants are thoroughly hoed, hilled, and irrigated. In October and November the leaves are stripped off and the stalks are then cut and the hard outer covering is removed, and the remaining portion is then ground between rollers of stone or hard wood. The cane juice is then boiled in iron kettles till the granulation takes place, when it is placed in bags and pressed dry. The expressed sirup is used as molasses. Dry upland soils are required for the successful growth of the cane, and the expenditure of labor and fertilizers is as great if not greater than for any other crop. Great exertions are being made to promote the increased production of sugar, which will probably be in some degree successful. In fact, I am informed that large orders for the apparatus for sugar-making have been received from districts which heretofore have not grown sugar-cane.—*India Mercury.*

A SUBSTITUTE FOR QUININE.

The Colonist (a Demerara journal) states that it has received from Mr. Courtenay a sample of *Sulphas* of *Beberia*, which is an alkaloid obtained from the bark of the *Nectandria Rodiaei*, or *green-heart*. This tree grows as much in Surinam as in Demerara, and as it can be used as timber, it may be well to call attention to it. We therefore give the communication from the *Colonist*. "Mr. Courtenay has obtained in London 30s. 8d. per English pound, for this medicine, prepared by himself. He is convinced that by preparing it in large quantities it would be very advantageous and prove a remunerative industry, because the cost of the manufacture is small and the original material is now of no value. In a London circular the price of this substitute for quinine is noted at 4s.2d. per oz. It is an excellent febrifuge and largely used in the English army; but until recently it was cheaper to use quinine, simply because the preparation of Beberia was not so general as that of quinine. We believe that the bark of *green-heart* has occasionally been imported into England, in small quantities, for the preparation of Beberia; but up to the present time no efforts have been made, by larger importation, to obtain the benefits of an article which is yearly thrown away in large quantities. *Apropos* of the above, the *Nieuws van den Day* gives the following:—The *Nectandria Rodiaei* growing in Demerara is not the *green-heart* tree so well known by us, but is a *yellow-heart* found plentifully in the English colonies and there called *green-heart* and in French Guyana *cèdre jaune*. The *yellow-heart* is not often found in Surinam. It produces good timber for furniture and has a strong scent. The *green-heart* (*Bignonia leucoxylon*)—not to be mistaken for the English *green-heart*—grows abundantly, in all dimensions, in Surinam, particularly in Upper Para, and in the high ground of the Surinam River, and is much required for timber. The bark provides no drug like the *yellow-heart*. After the *brown-heart*, the *green-heart* is certainly the most durable of any Surinam wood. It is heavy, of a brown colour and difficult to be worked. The sawdust when fresh is of a bright green colour, but when mixed with lye it produces a red colouring substance.—*India Mercury.*

LIGHT AND DARKNESS FOR VEGETATION.

Cultivators, rule of thumb and scientific alike, have been so fully alive to the importance of light to Vegetation and produce, that they have too generally overlooked the place and power of darkness. Under certain circumstances, Nature herself teaches the importance of darkness as in the germination of seeds by covering them as a rule with the stimulating and protecting covering of rotten leaves. A good many seeds will germinate in the light, but they do so sooner and to better effect in darkness; still, even this fact is not taken full advantage of in practice, as whole ranges of seed-pots and pans placed in the light abundantly show. These not only occupy valuable space that might as a rule be filled with growing plants, but labour in watering, shading, &c., as well as time, are lost by sowing seeds in the light.

There is also another source of loss by this general practice; the seeds are covered too deeply for their safety, in order to exclude the light. Number of them are thus ruined and rotted. All these risks would be avoided by simply sowing seeds in a dark shed or closet. Many seeds will hardly need covering; all would need less if placed in total darkness. Of course they would require pretty close watching, and prompt removal to light so soon as fairly vegetated. The transition from total darkness to absolute light also needs to be very gradual; but this period is of very short duration, for it is astonishing how soon healthy and vigorous embryo plantlets get used to the light.

But what may be called dark culture has a far wider field than the mere raising of seeds. Its importance has long been recognised in the rooting of Dutch and other bulbs. With the compound object of fully developing roots, and holding the stems in check till these are formed, bulbs are plunged in total darkness. In this also we are but following the example of Nature: whence the success that has attended the practice of keeping bulbs in the dark through their preliminary stages.

The next great step in dark culture consists in the treating of buds and root-stocks in the same way as seeds and bulbs. Corresponding as they do to the latter to a great extent in structure and functions, they may be treated in a similar manner, and with equally successful results. Growth in darkness is no longer a matter of theory, but is very widely practised, and has proved a striking commercial success. Up to the present time perhaps it has been most widely applied to Lilacs, Spiræas, and Lilies

* Read at an Evening Meeting of the Pharmaceutical Society, April 4, 1883.

of the Valley. Most of the earlier white Lilacs, that fill the Parisian, and to a large extent furnish the English markets early in the season, are grown in the dark. English cultivators are now fast imitating the French example, and, as a matter of experience, we can affirm that Lilac blooms so grown are even more pure and delicate and of about the same sweetness as those grown in the light. It is said that the French blanch the Lilac so completely in forcing it into bloom that they care little whether the variety is white or not to start with. We have not found it so. The coloured Lilac grows pale when grown in the dark but has not the absolute purity of the white varieties. —*Gardeners' Chronicle.*

GREAT ORANGES.

One of my orange trees grows fruit of an extraordinary size. There is nothing peculiar that I know of in soil, drainage, or exposure, to have caused the unusual vigour shown by this tree. It was planted near my house 12 years ago, at the same time with other fruit seeds of various kinds, the results of which are around it in a very slow-growing Sapodilla, a rather small Shaddock tree, several Governor plums *(Flacourtia)*, a Rose-apple *(Jambosa)*, a flourishing Cinnamon tree on the opposite side of the roadway, a few star-apples (*Chrysophyllum Cainito*) and a number of Lemon trees—large bearers of coarse, thick-skinned fruit. A very shallow gutter was certainly dug two feet from the trunk, but this does not seem to have favourably affected other fruit trees of same age equally near to the slight drain. The tree has sent up a tall, open-branched, good-sized straight stem (whose height and girth I shall state in next issue) and evidently comes from a good stock. This, my boys tell me, is the third year of fair cropping, but planted in 1871—it yielded a few fruit in the Xmas season of 1879-80 in its ninth year. In the Xmas of 1880-81 it gave a heavy crop—all big fruit, weighing down the branches till they were like to break, and in that of 1881-82 a similar one of like big fruit. The present year's crop, 1882-83, fit for gathering during the last five weeks and finished with the half-dozen plucked on Sunday, 18th inst., has been only a small one, most of the fruit again very big, more resembling shaddocks than oranges, but of the few found on the tree on Sunday only one was of the great size of the bulk of the first two crops and the most of last month's. The others have been *appropriated*, I am sorry to say, without leave or asking, and in spite of protest and warning. I had waited for an opportunity to send a sample of these large fruit to a friend, and now that it had arrived on proceeding to pluck the cherished and as I thought saved fruit, I found the tree almost bared of them. The half-dozen weighed 5lb. 13 oz., an average of 15½ oz. per orange. The biggest weighed 20 oz. and was 13 inches round, and two others together weighed just 2 lb. For these weights and measurement I am indebted to my friend who kindly undertook to ascertain the facts for me and who will save the seed of the best fruit for planting, in the hope of obtaining by selection, repeated if possible, a large-fruited variety of orange. I should add, the oranges of this tree have a thick skin little inclined to turn yellow, but the flesh, as my boys assure me, is as sweet as that of other oranges here, and—as is well known to all who have tasted them—West Indian oranges are remarkably sweet and juicy. It is annoying (and worse) that greed and curiosity could not keep thievish hands from this tree, as I am assured that two of the missing oranges were some ounces bigger (heavier) than the big one taken to St. Anns on Sunday—at least 2 oz., and more likely 3 or 4 oz. If the latter, the biggest oranges of the season's crop weighed each a pound and a half! Several others were of a like size and no doubt weight, to that of 20 oz. Thus, a little miserable boyish pilfering has defeated the hope (the *present* hope at least) of obtaining a race of monster oranges.—C., Belmont, February 21, 1883.—*Trinidad Chronicle.*

CINCHONA MANURING.

SIR,—It is generally believed that the only manure for cinchona is cattle manure, and that it produces a slightly more rapid growth but does not affect the richness of the bark. Now, I determined to make some experiments of my own last year, in the following manner:—My estate is a little over 4,000 feet, a part of which faces the north, the remainder the east. I have two clearings of cinchona, a large one of succirubra and a smaller one of officinalis; the former about two, and the latter nearly three years old. In May of last year, I applied manure to an acre of each field, thus:

I divided each acre in two portions, as nearly as possible in half, and so had four divisions, two of succirubra, and two of officinalis. In one field of officinalis and one field of succirubra I put cattle manure about half a basket, while to the other two portions I applied castor cake and bone dust in the proportion of two-thirds and one-third.

The following was the result:—The officinalis, with cattle manure, in August made a great start, and grew rapidly in bulk till January, when it stopped, and began to shew red-leaf. Since then canker has broken out and is now rapidly demolishing the field, which threatens to become extinct shortly. The officinalis, unmanured, is only slightly affected, and the mortality has not been nearly as high as on the experimented patch alluded to. On the other patch of officinalis, with castor and bone dust, the trees have only progressed in the same manner as the unmanured officinalis, and the death rate is about the same as the surrounding field. The succirubra with cattle manure began to show increased signs of vitality in September and went on to December, when it hung back again, and is now about on a par with that around it, as though there had been a spurt and then a reaction. The castor and bone dust on the other patch of succirubra has had a most wonderful effect. The trees have not only increased rapidly in bulk and are still doing so, but they are now one healthy sheet of dark green than which none better could be desired.

At the same time the fatalities from canker have ceased altogether, and the patch in this, as in all respects, shows a marked difference from the succirubra adjoining it. I am still watching the fields as the experiment is still going on, and I intend to manure again shortly. It would appear as yet that cattle manure to officinalis is harmful instead of beneficial, while artificial manure produces no effect at all. On succirubra, cattle manure seems to have a temporary effect, but the reaction, when the immediate effect of the manure has ceased, brings it back to the state it was in before. To succirubra the castor and bone dust seem most beneficial, and if, after the end of the twelve months, the progress in the successful patch continues, I shall go in for a wide application of it, as I reckon it will make the yield almost a quarter as much again as it would otherwise have been. What the effect of the manure on the barks has been I do not yet know, but if it happens that succirubra bark is enriched as well as increased by the application of castor and bone dust, then I say an important discovery has been made, as, though renewing produces the first result, the combination of both has not yet been attained.

I forgot to say that the soil of the patches on which I experimented was a rather heavy, dark chocolate one, as it is on the whole of my clearings, with a good deal of rock scattered about.—CADENUS in "Ceylon Times."

RUBBER IN BRAZIL.

In the early morning, men and women come with baskets of clay cups on their backs, and little hatchets to gash the trees. Where the white milk drips down from the gash they stick their cups on the trunk with daubs of clay, moulded so as to catch the whole flow. If the tree is a large one, four or five gashes may be cut in a circle around the trunk. On the next day other gashes are made a little below these, and so on until the rows reach the ground. By eleven o'clock the flow of milk has ceased and the *seringueiros* come to collect the contents of the cups in calabash jugs. A gill or so is the utmost yield from each tree, and a single gatherer may attend to a hundred and twenty trees or more, wading always through these dark marshes, and paying dearly for his profit in fever and weakness. Our *mameluca* hostess has brought in her day's gathering—a calabash full of the white liquid, in appearance precisely like milk. If left in this condition it coagulates after a while, and forms an inferior whitish gum. To make the black rubber of commerce, the milk must go through a peculiar process of manufacture, for which our guide has been preparing. Over a smouldering fire, fed with hard nuts of the *tucuma* palm he places a kind of clay chimney,

like a wide-mouthed, bottomless jug; through this *boiao* the thick smoke pours in a constant stream. Now he takes his mould—in this case a wooden one, like a round-bladed paddle—washes it with the milk, and holds it over the smoke until the liquid coagulates. Then another coat is added, only now as the wood is heated, the milk coagulates faster. It may take the gatherings of two or three days to cover the mould thickly enough. Then the rubber is still dull white, but in a short time it turns brown and finally almost black, as it is sent to the market. The mass is cut from the paddle and sold to traders in the village. Bottles are sometimes made by moulding the rubber over a clay ball, which is then broken up and removed. Our old fashioned rubber shoes used to be made in this way. Twenty million pounds of rubber, valued at $6,000,000 are annually exported from Pará in the dry season; many thousand people are engaged in gathering it. But the business is altogether a ruinous one for the province, as Brazilians themselves are fully aware. The *seringueiro*, who gains two or three dollars for a single day's gathering, has enough, as life goes here, to keep him in idleness for a week; and when his money is spent, he can draw again on his ever-ready bank.

The present wasteful system is spoken of as follows:—The half-wild *seringueiros* will go on submitting to impositions and dying here in the swamps, until Brazilians learn that by purchasing this land from the government, and planting it in rubber trees, they can insure vastly larger profits, and do away with the evils of the present system. It is what must eventually be done. The rubber gatherers, in their eagerness to secure large harvests, have already killed an immense number of trees about the Pará estuary; they have been obliged to penetrate farther and farther into the forest, to the Tocantins, Madeira, Purus, Rio Negro, and eventually even these regions must be exhausted, unless they are protected in some way. The trees, properly planted and cared for, will yield well in fifteen years, and, of course, the cost of gathering would be vastly reduced in a compact plantation; half the present labor of the rubber collector consists in his long tramps through the swampy forest.—*Dominica Dial.*

CINCHONA CANKER.

With regard to the clay sub-soil theory, I have two patches of succirubra, growing side by side, on a *quartzy* ridge, one some 5 years old, and the other two. The 5 year old trees have stood two shavings, and are looking very healthy, while a considerable percentage of the two year old ones are sicklied over with the roseate hue of—death! There is neither clay nor water here, but good honest quartz, with healthy *old* trees, and sickly young ones beside them. Then again with respect to the "wet-feet" cause of canker, I have seen good and healthy trees growing close to, and I might almost say *in*, swampy ground, and not a sign of disease has *yet*—and I say again *yet*, for I don't think there is a tree positively safe from canker—come to change the aspect of affairs. Steep land, flat land, dry land, wet land, they all alike seem to afford the fatal facility for this complicated disease, and as I have tried to prove at all stages starting with the seed. "A hard sub-soil" impervious to water, is said to produce canker; but trees growing on 3 inches of soil on a slab rock, to a measure, negative this so-called cause; and also prove that shallowness of soil will not answer the question, as I have here shewn. If clay sub-soil produced the disease, a general death on such a plot of ground must be expected, and at an uniform age, *i.e.*, after all the roots had got down to the sub-soil; but this is contrary to experience. One of the most striking phases of canker is that, in a whole field wearing the gorgeous death banner, exceptional trees survive, looking all that could be desired in point of health. Can it then be said that the tree possesses a stronger constitution, and is therefore better able to withstand the plague that his killed its brothers in tribulation? I fear then, though we are well aware, nay, too well aware of the effect, we know nothing respecting the cause of this dire evil, that has blighted many fond hopes and clear anticipations. I hope from what I have said here that I have shewn "K. C. B." good grounds for *not* including canker, for at best I could only tell him what he already knows; but I trust that those who can do the subject the justice that it demands will make their observations public, so that an opportunity is afforded to those who study the matter to acquaint themselves with the experiences of many. It appears to me that, in considering the question: "Does cinchona canker in its natural habitat?" while we know very little as regards soil, temperature, &c., there, we overlook an important fact, viz., that thousands of seeds and seedlings must perish before even a single tree arrives at its full growth. This must be so, or a tree so prolific as we know the cinchona to be would produce such numbers as to smother each other; hence in the "struggle for existence," we find the "survival of the fittest," but at the cost of how many lives we know not. In our way of treating the subject, we grow a pound of seed, and hope to see so many thousands of *plants*, and a large proportion of *trees*. Such could scarcely be the case in its native state. Nevertheless, this does not explain away the why or wherefore of canker, as we know it in Ceylon; nor yet does it do away with a theory that presents itself, that canker *may* have been imported to the country. But asks "K. C. B.," and I own to being dumb to reply, "Is there any instance of a cultivated tree being attacked with a similar kind of canker to the bark?" I can only advance one reply, and that is that both animals and vegetables have their natural enemies, some in the form of blight, others in fungoid disease, or some possible physical ailment; so can we expect cinchona to be free? Agriculture alone has brought us into a closer sphere of observation, and hence diseases present themselves to view, merely because of their individuality, whereas, in their wild state, we know absolutely nothing beyond perhaps the name and use to which the tree or plant may be applied, on which we are questioned. —*Cor.* "Ceylon Times."

SETTING OUT OR DIBBLING PLANTS.

BY J. E. SCOTT, DEL.

It is an arduous task to set out a large number of plants in the spring in the usual manner. In order to make sure of suitable weather for transplanting, it is frequently important that it should be done very rapidly, and anything that will facilitate the work will be of value. I have found the implements illustrated of very great assistance in setting out such plants as sweet-potatoes, tomatoes, and cabbages. I do not know where they originated, but they have been in use by the truckers in this section for three or four years past; and as they can be easily made by any farmer of average mechanical skill, I will describe them with the aid of the sketches herewith sent. The wooden tongs, fig. 1, are about three

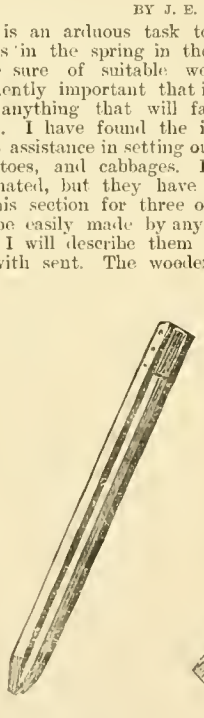

Fig. 1.—THE TONGS.

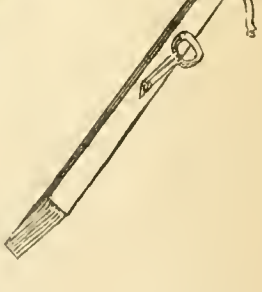

Fig. 2.—THE DIBBLE.

and a half feet long, and are made of two pieces of about the same width and thickness as ordinary lath; these are nailed at one end to a block about an inch thick and four or five inches long. This is used for picking up the plant before placing it in the ground. The hole for the plant is made with the instrument shown in fig. 2. This "dibble," or "dibber," is a piece, of yellow pine or ash, half an inch thick, three inches wide, and three and a half feet long; it is wedge-shaped at the lower end, where it is covered with sheet-iron or tin for a distance of five or six inches from the point, to prevent wear. A little above the middle, an

old fork-handle or shovel-handle is attached at an angle, and about three inches from the top there is fastened a strap, provided with a buckle, and long enough to reah around a man's arm.

The manner of operating is shown in figure 3. A boy drops the plants near the hills, and the operator following, seizes each plant in turn with the tongs, in such a way as to have the roots pointing downward. With his left arm he thrusts the dibble into the ground, and slightly turning the same, forms a hole for the reception of the plant. After placing the plant in the hole, the operator thrusts the dibble into the soil near the plant, its point near the lower end of the root, and pushes enough soil aroud the roots to complete the work. A good hand can set from 10,000 to 12,000 plants per day, and at the same time do it as well as it can be done in the old way and much easier.—*American Agriculturist.*

FAILURE OF THE TOBACCO CROP IN VICTORIA.

About one-third of the tobacco grown in the colony is produced in the Oxley district, and nearly the whole of the remaining quantity in the adjoining districts. The rich alluvial flats along the Ovens and King rivers, described in a former report upon hop-growing, constitute the tobacco land, being well suited for the growth of this crop; and it is estimated that between 500 and 600 acres of these flats have been devoted to its cultivation. The industry is also carried on upon the flats of Mitta Mitta, the Kewa, the Upper Murray, and on small alluvial patches in the direction, the whole area in these localities amounting to 600 or 700 acres, so that, including the Oxley district, there are in the counties of Dalatite, Bogong, and Benambra between 1,200 and 1,400 acres of land under tobacco, out of an estimated total for the colony of about 1,500 acres. Upon the Ovens and the King the crop this season is a total failure. There are only a few patches that will be gathered at all, and these will not yield more than 5 cwt. per acre. During my recent visit I saw a large number of plantations from which the tobacco had completely died away, and from inquiries made at Beechworh and Wangaratta, I am disposed to believe that the crops are nearly as bad in all parts of the north-eastern tobacco-growing districts.

A few years ago the industry was to a large extent in the hands of Chinese, but more recently, while Chinamen are extensively employed in the work, the plantations have more generally come into the possession of the European farmers. Much of the best land for tobacco-growing has to be cleared of timber, and much labour and attention has to be bestowed in cultivating and gathering the crop. As the work of cultivation was well suited for Chinese, many of the landowners let pieces of land to the Chinamen upon clearing leases, accepting a proportion of the crop as rent. A number of these tenants were prosperous, and purchased land of their own, while others selected small allotments of public land upon river flats, and while prices were encouraging, good progress was made. The system of giving a share of the crop to the Chinese who work the plantations is still carried out, but many of the European landowners now have the cultivation in their own hands, employing Chinese and other men as labourers. The failure of the crop, therefore, falls more heavily upon the Europeans than it would have done a few years ago.

The crop is well known to be an uncertain one, but it was generally reckoned that a good yield might be expected every third year, the intermediate returns being about half a crop. The yield was a light one last year, and owing to the low prices obtainable, a full crop was required this season to make up the growers' profits. A total failure is felt with intensified force. The failure was altogether unexpected, and its cause is not easily explained. Everything was favourable in the beginning of the season. The critical period of transplanting was passed through safely, and the plants for some time afterwards looked well, promising to turn out a fine crop. After the rains, however, which fell in October and during moist warm weather, known as "muggy," which succeeded, the plants became covered with a kind of blue mould, and ceased to make progress. Throughout the spring and summer there was no progress, but, on the contrary, the plants in many cases died quite away. It is certain that the failure was not from want of rain. Some of the growers believe there was too much rain in the summer, and others hold that the rain would have done no harm had the showers been followed by clear bright weather. There is no doubt that the blue mould which threatens the plant every year was the immediate cause of its destruction this season, the character of the summer weather being favourable to the growth of the disease.

The process of culture is to raise the plants in a seed bed, in the meantime preparing the land by ploughing and harrowing for receiving the crop. The free alluvial soil is worked into a fine tilth, and as the land is generally new, weeds are kept down with comparatively little trouble. In the month of October, and sometimes in September and November, transplanting takes place, the plants being about 4 inches long. Each plant is watered when planted out, and if rain soon follows all is well. This is the critical period, as, if it is not got over well, planting has to be done again. Should rain not come in time, however, the plants are sometimes kept growing by being again watered. As a general rule, when the plants start well after being planted out they make good progress until they reach maturity, but on this occasion, although all went well for a fortnight or three weeks after planting, an utter failure has resulted. When ready to gather the top is cut off the plant and the stalk is split down to within a few inches of the ground. Below this point the stalks are cut off and carried to large bark sheds, in which they are hung up to dry, the split stalks being hung across transverse wires or lines, the leaves drooping downwards. When sufficiently dry the leaves are stripped off and put into bales ready for market.

At one time the prices fluctuated to some extent according to the yield of the crop, so that when the crop was light the price was good, but the last change that was made in the adjustment of taxation and the relating to the manufacture of tobacco has had the effect of keeping the prices down. A number of small manufacturing establishments have been closed, and there are so few buyers that there is not sufficient competition among them to raise prices to a rate remunerative to the grower. The result is that the tobacco-growing industry stands in great danger of being extinguished. All the growers whom I met during my visit had decided to abandon tobacco culture for some more encouraging branch of industry. They stated that when prices varied with the character of the crop enough profit was made out of one good yield to recoup losses in less productive years, and there then was some inducement to continue, but with prices steady at from 5*d.* to 6*d.* per pound this was not the case. New land has to be cleared for the crop every second or third year, or heavy manuring must be resorted to. There is much labour involved in raising the crop and gathering it in, so that with the uncertainty of the yield the price obtainable is not considered remunerative.

About 13 cwt. per acre is regarded as a fairly good crop, and as much as 18 cwt. per acre has been sometimes obtained. The crop, however, is an exhaustive one, and could not be grown for more than three years without manure. Instead of manuring, however, the practice is to take in fresh ground, but this has to be allowed for in estimating the cost of producing of the crop. In addition to the low prices there is another thing which is likely to reduce tobacco in the market within very narrow limits, viz., the profitableness of hop-culture. As a general rule, the best tobacco-growing land is suitable for hop-gardens, and in a good many cases the tobacco-growers are about to turn their attention to hop-culture. There has been a demand for hop-sets all over the district, some orders coming from as far as the Upper Murray, so that a very large area will probably be planted this season—apart from the probability of an extensive abandonment of tobacco-culture next year, on account of the failure of the present season. Estimating last year's yield for the colony at about 700 tons, and reckoning that the loss in the Oxley district alone this year must amount to fully 150 tons, the year's total will show a serious falling off. Unless the crops on the Mitta Mitta, the Upper Murray, and other rivers in those localities are much better than they are represented, the yield of the colony will not be more than 300 or 400 tons, or even less.—*Australasian.*

THE ORIGIN OF CULTIVATED PLANTS.

From a review in *Nature* of De Candolle's latest work, we extract some very interesting details:—

"An English vegetable garden," says Mr. Tylor, "is a curious study for the botanist, who assigns to each plant its proper home; and to the philologist, who traces its name." But De Candolle, not confining himself to our temperate pot-herbs, has included in his studies the cultivated plants of all countries. Accurate knowledge in this matter is a thing of comparatively recent growth. Linnæus bestowed no pains upon it. Humboldt in 1807 dismissed it as an impenetrable secret. De Candolle has now discussed no less than 247 species. It is curious—perhaps significant—to note that 199 of these trace back to the Old World; only 45 are American, and 3 doubtful. Neither the tropical nor the southern regions of either hemisphere have any of these species in common. The northern have five which are so, but it goes with the rest of the facts that the domestication of these belongs to the Old World, and to this De Candole has accordingly credited them. Some things no doubt have escaped him, although the list is remarkably complete. Perhaps the most curious omission is rhubarb, the use of which for the table seems pretty much confined to England and Holland.*

It is rather to be regretted that De Cand9lle has abandoned the attempt to indicate the points on the earth's surface from which the maximum number of cultivated plants appear to have sprung. He contents himself with saying that the original distribution of the stocks of cultivated plants is most irregular. "It had no relation with the needs of man supplied nor with the area of origin." I have a decided suspicion that the facts might be made to yield a different result. There does not seem any *a priori* reason why plants susceptible of useful development under cultivation should be so arbitrarily distributed. The number of species domesticated in a given area would, other things being equal, seem to be related to the intelligence of the races working on them. North America has only given us the vegetable marrow and the Jerusalem artichoke; and neither deserve more than a *succés d' estime*. But our best domesticated plants have developed their merits *pari passu* with the races that educated them. If we stumbled *now* against the primitive stocks they might seem as little susceptible of development as the plants of the United States, whose capabilities we rank so low. But had the Old World races been but early enough on the New World soil to work out their progress to civilization, possibly the balance in the proportion of domesticated plants would have been redressed. If the gardens of the United States are filled with Old World vegetables, the houses are inhabited by an Old World stock. The two things seem to me to go together; the indigenous races could neither develop their latent vegetables nor hold their own against an Old World human invasion.

The circumstances of domestication, however, impose certain conditions which the flora drawn upon must fulfil. The early stages of civilisation were probably unsited to any fixity of abode. Tylor, it is true, remarks that "even very rude people mostly plant a little." But they will plant only what will give a quick return, and the qualities of foresight as well as a permanent social structure must be developed before men would have the disposition to plant fruit trees, which perhaps only their descendants would gather from. The first domesticated plants must have been those that were in themselves succulent, or would in the course of a single season yield some desired product. We find then that out of the 44 species, the cultivation of which in the Old World goes back to the dawn of civilisation, half are annuals; and these are just what the great temperate flora of the northern hemisphere would supply. On the other hand, Patagonia and South Africa have not yielded a single domesticated plant. Australia only contributes the overrated *Eucalyptus globulus*, and New Zealand a wretched spinach (*Tetragonia*). But then, as De Candolle remarks, their floras are destitute of the types of *Gramineæ*, *Leguminosæ*, and *Cruciferæ*, which were available in the northern hemisphere, and predominate in the list of the 44 most anciently cultivated plants. As between the north and the south I think this argument is valid. But as between the east and the west in the north hemisphere, since the main features of the flora are radically the same, any similar explanation does not hold.

With regard to such of these primitive cultures as belong to the temperate regions of the Old World, it will be interesting to give De Candolle's conclusions. The turnip and rapeseed (not however sustainable as distinct species) originated in Northern Europe. The cabbage was derived from the western coasts of Europe, where its wild stock may still be found; it was first gathered and then cultivated by pre-Aryan races. Purslane is wild from the Western Himalayas to Greece. The onion was brought from Western Asia. As to textiles, the origin of flax is somewhat complicated. The inhabitants of the Swiss lake-dwellings of the Stone Age did not use our present annual flax but a subperennial sort indigenous to Southern Europe (*Linum angustifolium*). This was displaced by *Linum usitatissimum*, a native of countries south of the Caspian, which was introduced into Europe and India by Aryan races. The knowledge of hemp seems to have been brought into Europe by the Scythians about 1500 B.C.; there is no trace of it in the Swiss lake-dwellings. The vine is indigenous in Western Asia, whence its use was carried to various countries by both Aryan and Semitic races; but it did not reach China before 122 B. C.

The almond, although so characteristic of Mediterranean countries, seems to be a native of Western Asia, and perhaps Greece. As late as the time of Pliny the fruits were known to the Romans as *Nuces græcæ*. The wild stocks of our pears and apples seem to have been indigenous to Southern Europe and Western Asia before the Aryan invasion; their remains abound in the Swiss lake-dwellings. The quince is a native of North Persia, but seems to have been introduced into Eastern Europe in pre-Hellenic times. Remains of a form of the pomegranate have been found in strata of the Pleiocene age in Southern France by Saporta; but it died out and was reintroduced from countries adjoining Persia in prehistoric times into the Mediterranean region of which it is now so characteristic a feature. The primitive home of the olive was apparently the eastern shores of the Mediterranean, where the Greeks discovered its useful qualities, the Romans learning them later. The fig has left its remains in quaternary rocks in France along with the teeth of *Elephas primigenius*, but its prehistoric home must be sought in the Southern Mediterranean shores and lands, where it survived after probably perishing in France. The common bean (*Faba vulgaris*) seems to have become extinct in a wild state; it may have originated south of the Caspian, and was introduced into Europe by the Aryans. The remains of lentils have been found in lake-dwellings of the Bronze Age, and it was probably indigenous in Western Asia, Greece, and Italy before its cultivation in these countries; subsequently it was introduced into Egypt. The chick-pea was carried from the south of the Caucasus by the Aryans to India and Europe. The carob is indigenous to the Eastern Mediterranean, whence the Greeks introduced it into Italy and the Arabs into Western Europe. De Candolle regards all the various kinds of wheat as derivatives of the small-grained kind found in the most ancient lake-dwellings of Western Switzerland. He inclines to the belief that the wild stock of this originated in Mesopotamia, where it may still exist. The origin of spelt is very doubtful, and it may possibly be an ancient cultivated derivative from the wheat stock. As to barley, the inhabitantsand the Swiss lake-dwellings cultivated both the two-rowed of the six-rowed kinds. The former is found spontaneously in the area between the Red Sea and the Caspian; but nothing is known of the spontaneous occurrence of the latter or of the four-rowed kind. Either then both were derivatives in prehistoric times of the two-rowed variety, or they are the cultivated representatives of species which have since become extinct. As to rye, probability points to an origin in South-Eastern Europe. The lake-dwellers even of the age of Bronze did not know it, but Pliny mentions its cultivation near Turin. De Candolle supposes that the Aryan migrations westward met with it in Europe and carried it onward. Oats seem also to have originated in Eastern Europe; they are found not earlier than the Bronze Age in Switzerland. From Pliny's mention that the Germans used oatmeal, it is concluded that it was not cultivated by the Romans.

* No: in the United States they call it "the pie plant."—ED.

TREES OF MADAGASCAR.

The soil of Madagascar is very fertile, and produces rice, maniok, sugar-cane, pepper, cotton, indigo, tobacco, as well as a number of medicinal herbs. A chain of high mountains divides the country into several well-watered valleys. The most beautiful feature in the island is the imposing forests which extend over a distance of two thousand English miles and contain fine and valuable trees covered with rare climbers and orchids. Among the trees are found pandanas, acacia, sago and the cocoa nut, but above all is the ravinda (*Urania Speciosa*) which of itself forms large forests. The Rev. W. Ellis says of this tree:—It springs up with a thick, juicy stem similar to the Banana (*Musa Sapientum*), in the centre of it are broad leaves which resemble the Banania but are less brittle. The leaves surround the stem in rows on opposite sides, and by increasing and leaning over those underneath, the tree assumes the shape of a large open fan. I have counted, on more than one occasion, twenty to twenty-five leaves on one tree. The stalk of the leaves is from six to eight feet long, while the broad leaf itself is from four to six feet long. The bright green leaves, extending themselves like a fan, form the most beautiful plant that can be imagined." But it is not only for its beauty that the tree is remarkable. It is used for many purposes, in the same way as the palm tree is in the Arabian desert; but one of its most important properties is that during the dry season it contains a large quantity of fresh and pure water, and is thus a refreshing spring for the thirsty traveller. The reservoir is situated at the base of the stalk of each leaf, and, upon being opened, a stream of cool and sweet water appears. The natives use the leaves of the tree to cover the houses, and the bark for flooring. At most of the markets there are sold articles made from these leaves, comprising plates, dishes, table cloths, napkins, etc., and even spoons and tumblers, but for these last articles the leaves are specially moulded.—*India Mercury.*

AGRICULTURAL "FADS."—Among the many "fads," which Mr. Angus Mackay used to expatiate on with so much gusto, was the Scuppernong grape, which we were asked to believe, some twelve or fifteen years since, was a most valuable addition to our then known vines. We saw one of these at Carlsburg the other day. Like one or two we have seen elsewhere, it has never borne but one or two berries, nothing approaching a bunch ever having been seen upon it. This American creeper is a fit companion to that English weed—the prickly comfrey, which we were told was so valuable as a forage plant.—*Planter and Farmer.*

HOT WATER AS AN INSECTICIDE.—J. W., Liverpool, writes:—"Last spring I read in the Journal that the best way to get rid of insects destructive to Orchids was to plunge the pots in hot water at a temperature of 120°. I was rather in doubt whether it was safe to do this, consequently tried two or three pots that I knew were pretty well full of woodlice, or, perhaps I should say, appeared so from the condition of the roots. The contents of these pots all changed, the insects were killed, and the Orchids improved. Seeing that no injury was caused to the plants, I last August plunged every Orchid I had in water heated to 120°. I have found that it has not injured one plant. Dendrobium densiflorum that I subjected to this treatment has now no less than forty-two spikes of bloom, and these in a few days will be fully expanded.—*Journal of Horticulture.*

NEW PRODUCTS.—The Hon. John Douglas, C.M.G., during his recent visit to Bundaberg—where we notice he became a purchaser in the new Barolin township—collected a quantity of a certain weed, which is stated by him to be becoming very prevalent in the Woongarra Scrub, and the root of which grows to the size of beet-root. Mr. F. M. Bailey, the Government Botanist, to whom he submitted it for inspection, says it is the first specimens of the plant he has seen. He states it to be the Virginian Poke (Phytolacca decandra, Linn.). It is said that the berries were at one time used in Portugal to give the deep colour to red port. The root is emetic, nearly like ipecacuanha. Some say that when properly prepared it operates in the same doses with the same certainty; exteroally applied, it is said to cure psora and tæniacapitis, whatever those ills of humanity may be.—*Planter and Farmer.*

THE PHYLLOXERA.—According to the last report of M. Tisserand, Director of Agriculture, cited in the *Revue Horticole*, no fewer than fifty departments of France are invaded by Phylloxera, 764,000 hectares of Vines entirely destroyed (a hectare=about 2½ acres), 642,000 hectares more or less seriously affected.—*Gardeners' Chronicle.*

NEILGHERRY CINCHONA.—The following facts are interesting in connection with Mr. John Hughes' paper upon Neilgherry cinchona soils, recently published by us:—"The Madras Government some time ago forwarded to the Secretary of State consignments of cinchona bark from their estates at Naddewatum, Dodabetta and Pykara, from which quinine and other alkaloids were to be manufactured on their behalf. These barks were made over to Mr. Whiffen, the well-known pharmaceutical chemist, and the analysis yielded the following results:—

Description of bark	Quinine sulphate per ct.	Cinchonidine sul-phate p. ct.	Cinchona alkaloid p.ct.
Renewed crown...	5·57 to 5·71	0·41 to 0·48	0·12 to 0·31
Mossed...	4·06 to 4·03	1· 0 to 1·05	0·02 to 0·24
Natural	3· 6 to 3·42	1·02 to 1·21	0·15 to 0·23
Renewed red ...	3·04	2·32	1·84
Mossed...	1·71 to 2·09	2·15 to 2·32	1·68 to 2·39
Natural	1·28 to 1· 2	2· 8 to 3·57	1·14 to 1·63
Root	1· 3 to 2· 9	2· 1 to 2·15	2·39 to 2·57
Branch	0· 8 to 0·66	1· 5 to 1·35	0·47 to 0·51
Renewed scraped crown	4·34	0·37	0·21
Natural scraped...	1·81	0·75	0·06
Branch crown...	0·07	0·16	0·04

The total of products obtained by manufacture was as follows:—

Quinine sulphate	1,467 lb.
Cinchonidine sulphate...	345 „
Quinidine „	40 „
Cinchonine alkaloid	208 „
Febrifuge	2,236 „

Total charges on account of the bark sent amounted to £3,352 0s 9d, distributed as follows:—

Freight Agency, &c.	721	9	3
Manufacturing charges	2,604	11	0
Fire Insurance of bark at factory... ...	26	0	0

—*Planters' Gazette.*

RUBBER IN BOLIVIA.—The recent extraordinary rise in the price of Para rubber, and the manifest need of a new source of supply for that valuable commodity beyond the control of the parties who have cornered the Brazilian supply, serve to bring to notice the promising rubber district explored by Mr. E. R. Heath, in Bolivia, two years ago. He describes the Beni River as navigable by large steamers for a distance of 525 miles from its junction with the Mamore, and for 300 miles more by craft of less than three-feet draught. The forests on both sides of the river are full of rubber trees, offering a supply of rubber "practically inexhaustible." On the north side of the Beni River the forest extends from the water's edge over fifteen degrees of latitude. Mr. Heath penetrated this dense forest at one place as far as twenty-one miles from the river, and the further he went inland he found the rubber trees increase in size and number. Each square league contains from 300 to 5,000 trees. On the south side of the river, the forest is only from three to ten miles wide, but it abounds in rubber trees. The supply of the rubber, Mr. Heath says, is sufficient to give employment to 100,000 men, and as soon as the chain of communication by steamer and railway is completed, that number of men will soon be engaged in that field of labour. The rubber, though at present commanding only the same market price, is of a slightly finer quality than that obtained from the old-established districts between the falls and the month of the Madeira River, and on the river Tapajoz and other tributaries of the Amazon near Para. It possesses other more important advantages over the older districts. The climate is healthy. There is an abundant supply of cheap labour at hand, the Indians obtained from the department of the Beni, who are practically slaves, working at from 10s. to 14s. a month. The abundant supply of palm-nuts which are used in smoking the rubber—a necessary process previous to evaporation—enables the collectors to work ten months out of the twelve, instead of six, as in the other districts.—*British and Colonial Printer.*

Sap.—Seeds should not be much more than half dried and dry grass or paddy straw should be strewn over the ground after planting them. When planted, they should be freely watered. The outer shell and inner soft covering of the seed may be found to have rotted, but that would not indicate the germ was dead.—*Cor.*

New Kinns of Tea.—Mr. E. Colborne Baber, while Consul at Chung King, described a few of the wild teas of Szechuen in Western China, which evince peculiarities of considerable interest. During one of his rambles the monks of the Ngomi monasteries refreshed him with a naturally sweet tea which tasted like common Congou mingled with brown sugar. The tea seems to be found only on the slopes of this range, as inquiries a few miles distant failed to produce any recognition of it among the natives. Another kind was met with in the wilderness of Hwang-muchang plateau overhanging the Tung river at a height of 6,000 ft., which yielded a highly coloured, but somewhat weak infusion, having the taste and flavour of tea and milk mingled together. The plant is described as a leafy shrub 15 feet high, with a stem some four inches thick, every portion of which, except the roots, is used in preparing the beverage.—*Indigo Planters' Gazette.*

Gold in Fiji.—The tidings from Taviuni give the impression that the gale of the 12th and 13th has been most severe to windward. At Vuna Point the force of the wind was not excessive, and no damage of any kind was done, but at the north end residents of many years declared it was the most severe blow they could recollect. To cocoanut, palms, breadfruit and other trees, very serious damage was done. Some places the cocoanuts were snapped off through the middle, in others the younger trees were blown clean out of the ground. Qamia, and particularly Laucala, have especsally suffered most severely, the fine breadfruit trees on the latter island being nearly destroyed. Coffee escaped without very serious hurt, but tobacco, of which very large quantities had been planted this year, has been very severely handled. Of this crop the portion approaching maturity was almost destroyed, but to the young, immature plants, less damage was done.—*Fiji Times.*

Sugar in Cuba.—In a recent report of Acting Consul-General Carden, on the "Number and Condition of the Slaves in Cuba," the following mention is made of the Sugar industries:—"But besides these there is another and perhaps a somewhat unexpected reason why there should be fewer emancipations in the country districts. I allude to the disinclination of many slaves to leave the place where they have been born and brought up and have their families, unless driven to it by very harsh treatment. It should be borne in mind that on almost all Sugar estates the negroes have their little plots of land, on which they grow vegetables and raise fowls and pigs, often selling them to their master himself; indeed, it is rare to find an estate where the industrious ones have not at least 50 or 100 dollars laid by. Now that, besides these little earnings, they are receiving wages as well, I am convinced that, were it not for the restraining influences of locality and custom, many more would avail themselves of the power they unquestionably have to purchase their freedom, which year by year it is becoming easier for them to do, and I am inclined, therefore, to think that the fact of their not doing so more proves they are, on the whole, fairly treated.—*Produce Markets' Review.*

Imitation Aromatic Woods.—Our readers may not be aware that not one out of ten of the so-called camphor-wood boxes imported from China and sold in India is made of the genuine material. The imitative faculty of the celestial is proverbial, and in this branch of industry—the manufacture of imitation camphor-wood boxes—it has been exercised with a high degree of success. For these same spurious boxes are greatly in request as cheap substitutes for the comparatively scarce and more costly article. The operation is very simple—the application of camphor oil to any wood capable of absorbing it, but more especially to those varieties of timber which, in appearance, colour, and grain approach the camphor laurel. There are two species of the camphor tree, viz., the Chinese and Malayan, the product of the latter (which is found in a natural state) being a hundredfold more valuable than that of the former. We have, here in Southern India, an analogous ease of the similar impregnation of woods with essential oils derived from other trees. This is notably exemplified in the *carved* cabinets, work-boxes, picture-frames, &c., exposed for sale as sandal-wood—whereas, in most instances, the articles in question are made of a very different wood, and are only smeared or coated with the perfumed extract or essential oil of the sandal-wood tree.—*Madras Times.*

Working the Soil.—Farmers are frequently met with who object to stirring the soil among growing crops, or knocking it about very much previously to sowing the seed, from the fear that they will exhaust the moisture by so doing and spoil the crop. An American exchange says:—"Professor S. W. Clark, Spencerport, New York, reports a farm neighbour as preferring to give up manure rather than frequent tillage. Mr. Henry U. King, of West Walworth, says he cultivated a field of corn six times the past very dry summer, and the crop was one of the best he ever had. 'Thorough working of the soil,' he finds, 'neutralises the effect of the drought.'" Many of the shallow theories which readily lodge in the minds of colonial farmers, and influence their operations continually, are totally at variance with fact, and so men would find if they would venture on a little experiment. Pulverising and frequent stirrings of the soil create rather than dissipate moisture.—*Queenslander.*

Royal Horticultural: *March* 27.—*Scientific Committee*:—Sir J. D. Hooker, K. C. S. I., in the chair. Present—Messrs. G. Henslow, R. MacLachlan, W. G. Smith, Geo. Murray, Arthur Grote, Professor Church, Drs. Low and Masters. *The Papaw and its influence on Meat.*—Rev. Geo. Henslow spoke of experiments he had made with the leaf of the Carica exhibited at the preceding meeting with a view of testing its alleged power of softening meat. Some beef-steak was wrapped in the leaf for twenty-four hours, a corresponding portion being placed by its side under like conditions except as to the leaf. When both were cooked it was found that the steak wrapped in the Papaw leaf was markedly more tender, but had acquired a peculiar flavour. *Coccus on Orange Trees.*—Mr. McLachlan read a communication from the Government of the Bahamas with reference to the cocus scale on Orange trees, which was proving so destructive in those islands. The insect in question is Mytilaspis citricola, one of the Coccidæ. Washes and syringing with petroleum prepared, and the use of whale-oil soap were found to be the most serviceable.—*Gardeners' Chronicle.*

Papaw Juice.—Among new and interesting substances which have come prominently forward within the last year or two, we should mention papaw juice, which is the juice or milk of the fruit and bark of the *Carica papaya*, a tree to which attention was first called, in this particular respect, in the year 1875, on account of the wonderful digestive powers ascribed to the said juice. The tree is said to grow plentifully throughout the Brazils and in the West India Islands. It will be remembered that M. Wurtz, of Paris, professor of chemistry at the school of medicine, drew attention lately to the active principle, *papaine*, extracted from the juice of this plant, and that its solvent or digestive action is said to extend to the pseudomembrane of diphtheritic affections. The milk or juice is now to be met with in the American market, but it is sad to be an unstable and unreliable article, which no one will be ready to deny. Papaine which can also be extracted from the leaves of the tree is supposed to be preferable. The powerfully caustic or corrosive action of the crude article requires that it should be used with all due care, especially if given as an internal remedy. It already goes by the name of "vegetable pepsine," which of course behoves double caution on the part of the physician who prescribes it either internally or externally. No doubt is entertained by many able pharmacists that, at no very distant future, it will find a useful place in pharmacy. In the meantime, an enterprising manufacturing chemist has placed in the market a soap for cleaning and softening the skin, which it is believed contains papaine in a mild from. The experiments carried out at some of the Paris hospitals where this active principle was used in place of lemon juice or hydrochloric acid to dissolve and detach diphtheritic membrane, appeared to promise most satisfactory results, but, on the whole, no marked advantage appears to have been gained by its use.—*Monthly Export Prices Current.*

THE Swedish Government has granted a sum of £60 for this year, to an entomologist, whose duty it will be to advise farmers as to the best means of destroying injurious insects.—*Nature.*

THE TARO PLANT, which constitutes the principal article of diet amongst the natives of many of the South Sea islands, has been cultivated for years on many of the sugar plantations of this colony for the use of kanakas. It has not come into general consumption amongst the white population, although it is said to be a very healthy vegetable, equal, if not superior, to the sweet potato. It has recently been introduced into some of the Southern States of America, where it is not only relished as a vegetable, but has been found a most excellent food for horses and cattle. The taro grows to greater perfection in the island of Tanna than in any of the other islands, on account of the great depth and freeness of soil in that island. The natives cultivate it, like the yams, on the tops of mounds of finely pulverised earth. When grown on land cultivated by the plough, it is usual to plant it on the tops of large drills prepared by hilling up together three or four furrows. A very good starch and a very fair arrowroot are made from the bulb. It can only be cultivated with success, however, on fine alluvial soil such as are to be found along the banks of rivers in this colony.—*Queenslander.*

COCO-NUT FIBRE for potting Cattleyas and other Orchids has been tried at Broomfield, Chelmsford, with the most lamentable results. When, with Mr. Warner, over twenty years ago we made a series of very careful experiments with the whole husk, the roughly broken husk and the fibre, and the result in each case proved that the end thereof was death to all the Orchids experimented on if they were not shaken out and repotted in the usual way. Notwithstanding these experiments, Mr. Warner has recently used it largely, and it has proved an expensive experiment to him, as it will to all who are beguiled into trying it. It is strange that these pranks should be played always by old and clever growers; one seldom sees the beginner depart from the tried and proved methods. A few years ago I saw a very large collection reduced to misery by the use of coco-nut fibre mixed with sphagnum, and since that I saw that the grower who had produced some of the finest specimens in the North when he used peat and sphagnum, had potted a great number of his plants in sphagnum mixed with what seemed to be road scrapings. My experiments show that, when kept dry, cocoa-fibre gets covered with a white mould, and when wet with a gelatinous fungus, either of is poison to the roots. When dry it is next to impossible to thoroughly wet it, and the harsh fibres cripple the roots wherever they touch them. If any one wants to earn a testimonial from the Orchid growers let him tell them where they can get the good old Orchid peat they used to get: there must be plenty of it in the British Isles. I have seen fine samples from Sweden and Norway: if it cannot be got here, I think it would pay some one to get some over.—JAMES O'BRIEN.—*Gardeners' Chronicle.*

PINEAPPLE CULTURE IN QUEENSLAND.—Very few people have any idea of the possible yield with pineapples where the climate and soil favour their production. It has been recently stated by a Mr. Rodda, after an inspection of a pineapple patch, that an acre of soil would yield over 10,000 fruit in the season, and, where a plantation is well established, and the plants in their prime, this is not an over estimate. On an average of 5ft. from plant plant an acre would carry 1,750 plants per acre. The first year two to each plant would be a good yield, the second year four or six, and after that strong plants will often give from eight to twelve pineapples in the year, if not all at one time at intervals during the season. So then the first year's yield would be 3,500, the second year from 7,000 to 10,000, and the third year, if eight or twelve fruit were produced on each stool, the yield would be 14,000 or 21,000. Startling though these figures may appear, they are quite within reach with good cultivation; with the neglect so frequently attendant upon pineapple and banana culture, however, the half of this is a high average. But taking 10,000 as an average crop, and the low rate of 1s. per dozen as the market value, one acre of pineapples would realise over £40, which is a good return for the labour and outlay necessary to produce them. It has always been a matter of surprise to us that the cultivation of this delicious fruit has been so much neglected, especially when the fact, so frequently brought to light, that Queensland-grown pineapples are equal, if not superior, to those grown in Florida or elsewhere is taken into consideration. The cultivation necessary for a five-acre plantation, and everything to be done efficiently, could be easily compassed by one man, breaking the land up deeply in the first instance with the plough followed by the subsoiler. Coast lands in Southern Queensland are very well adapted for this fruit if the soil is deep, rich, and drained thoroughly.—*Queenslander.*

WHAT LEAVES ARE TO TREES, is shown, and the disastrous influence of leaf disease, on tree life can be inferred, from the following introductory paragraph to an article in *Nature*:—"The leaf is the essential and really active part of the ordinary vegetal organism: it is at once the mouth, the stomach, the heart, the lungs, and the whole vital mechanism of the entire plant. Indeed, from the strictest biological point of view every leaf must be regarded as to some extent an individual organism by itself, and the tree or the herb must be looked upon as an aggregate or colony of such separate units bound together much in the same way as a group of coral polypes or the separate parts of a sponge in the animal world." The writer, Mr. Grant Allen, goes on to describe the functions and food of leaves after a fashion calculated to impress us deeply with the importance to a tree of a plentiful supply of healthy foliage. We confess that we never, previously realized so vividly the value of carbon as plant food. "The great function of a leaf is the absorption of carbonic acid from the air, and its deoxidation under the influence of sunlight. From the free carbon thus obtained, together with the hydrogen liberated from the water in the sap, manufactures the hydrocarbons which form the mass of its various tissues. Vegetal life in the true or green plant consists merely in such deoxidation of carbonic acid and water, and rearrangement of their atoms in new forms, implying the reception of external energy; and this external energy is supplied by sunlight. We have thus two main conditions affecting the shape and size of leaves; first, the nature and amount of the supply of carbonic acid; and second, the nature and amount of the supply of sunshine. But as leaves also aid and supplement the roots as absorbers of water, or even under certain circumstances perform that function almost entirely alone, a third and subordinate element also comes into play in many cases, namely, the nature and amount of the supply of watery vapour in the air. This last element, however, we may leave out of consideration for the present, confining our attention at the outset to the first two. Carbonic acid is the true food of plants: water, one may say, is only their drink. The roots can almost always obtain a sufficient amount of moisture; and though no doubt there is sometimes a fierce struggle for this material between young plants, yet its effects are not usually so obvious or so lasting on the shape of the parts concerned. But for the carbon of which their tissues must be built up, there exists a competition between plants as great and as evident as the competition between carnivores for the prey they persue, or between herbivores for the grasses and fruits on which they subsist. The plaint endeavours to get for itself as much as it can of this fundamental food stuff; and all its neighbours endeavour to frustrate and to forestall it in the struggle for aërial nutriment. Again, the carbon is of no use without a supply of sunlight in the right place to deoxidise it and render it available for the use of the plant. Hence these two points between them mainly govern the shapes of leaves. Natural selection insures in the long run the survival of those types of foliage which are best fitted for the performance of their functions as mouths and stomachs in the particular environments that each species affects. Accordingly, in the final result each plant tends to have its chlorophyll disposed in the most economical position for catching such sunlight as it can secure; and it tends to have its whole absorbent surface disposed in the most advantages position for drinking in such particles of carbonic acid as may pass its way. The importance of the first element has always been fully recognised by botanists; but the imoprtance of the second appears hitherto to have been too frequently overlooked."

TEA CULTURE IN DARJILING, SYLHET AND CEYLON.

When in the Darjiling district in March 1876, we examined with special interest the more elevated tea estates with reference to the question of tea culture at high altitudes in Ceylon. The highest estate of all was one close to the station at an elevation of nearly 7,000 feet, being the property of the late Mr. David Wilson of Calcutta. The feeling then was strong as to the unprofitableness of estates at any higher altitude than about 3,000 feet: the idea being that the lower the better and the flatter the more productive. We learn that there has lately been quite a revolution of feeling in regard to altitude in the Darjiling district. Not only have the high estates yielded much better than was expected, but they have been free from the plague of red spider, which has ravaged the lower estates. As 3,600 in Darjiling is the equivalent of 5,000 in Ceylon, it is obvious that, if estates at and above 3,600 feet in a locality 27° from the equator give good results, we may very safely go up to 6,000 feet and over in Ceylon. The yield of tea per acre may not be equal to that obtained in "lowcountry" places, but not only may the quality be finer, but there is the grand consideration of a climate most favourable to human health, with, probably, immunity of the tea-plants from blight.

We have had a call from Mr. Constable Brown of the Sylhet district on his way home, and he informs us that the plantation he was on—he mentioned the name, but we forget it—has 200 acres planted with tea, of which 90 are in bearing, and from this portion there has been gathered the biggest return this year recorded for the Indian districts. From 54 acres on the flat he gathered 10 maunds (840 lb.) per acre all over, and from 36 acres of hilly ground an average of 8 maunds (672 lb.), and all this tea was delivered in Calcutta at 5 annas 9 pies per lb., the exact equivalent of 36 cents. Of course, the splendid yield reduced the average cost per lb., but Mr. Brown says that in Sylhet with cheap water carriage, and so far as he knows a fairly good labour supply, many of the planters aim at a reduction even on this rate, and he added that one large firm who are opening 1,500 acres this year base their estimate on a cost of 5½ annas or 34·37 cents per lb. in Calcutta. Mr. Constable Brown had visited our hill country when Windsor Forest was being planted, and he then expressed a favourable opinion about the growth of tea in the Dolosbage district, but he has a strong opinion in favour of flats and against sloping ground, based no doubt on his own favorable experience on flat land in Sylhet. On the other hand, a gentleman with Assam experience declares that the draining of "flats" costs a large sum there. Of course the Sylhet returns mentioned are far above the average—being the season's maximum—for the Indian districts; but, if Mr. Cameron is a true prophet, we may hope to see a considerable area in Ceylon yielding 8 maunds and upwards; while already it is stated that the tea from a well-known Ambagamuwa property (all sloping land and 3,000 feet above sea level at least) is being delivered in Colombo at a cost of 30 cents per lb.

On the other hand we have heard the question of labour supply for Ceylon tea estates debated as one of serious moment in connection with the future success of the enterprize. The argument is put in this way:—"In the busiest and most prosperous days of coffee planting, one cooly per acre per annum was an ample supply to bring in the biggest crop. But for tea, it would seem to be a case of 3 or 4 hands to the acre in the height of plucking (if from 600 lb. upwards are to be gathered); and so, if plucking is to be continued for 8 or 9 months of the year, where are the hands to come from, when we have 150 000 acres under tea? At this moment with the scant cooly supply it would be difficult to overtake 50 000 acres of tea in bearing." Our answer to this is:—Would that the Colony had a crop to gather today beyond the visible supply of hands—the coolies would quickly be found, or Sinhalese brought in to help,—if there only was the leaf available. Taking averages however and supposing that coffee in bearing required ¾ cooly per acre and that tea will take 1½ all the year round, the difference in the demand for labour for the two industries will no doubt be considerable. But are not the Sinhalese men, women and even children specially fitted to be tea pluckers? We believe the Dolosbage tea planters say (at least Mr. Blackett is confident) that as many Sinhalese could be got for their requirements as may at any time be required, and no doubt this will hold good of districts lower down all the way to Morawak Korale and Kalutara. Indian coolies too will very speedily find their way back to Ceylon when they hear that there is *crop*-(whether leaf, or cherry, or pod, or bark, or rubber juice), which means money, to harvest. We have no fear therefore that this Colony will be in difficulties from shortness of labour supply for tea or any of the new or old products.

It was startling to see Mr. Tom Gray the other day, calmly stating that he had pruned and was plucking two-year old tea trees. It is laid down in books on Indian tea planting that tea bushes should not be subjected to even light plucking until their third year. But then in India age is computed from the date of putting the seed into the nursery. So that to Indian planters Mr. Gray's plants would be three years old. Nevertheless it would stagger an orthodox Indian planter to hear of three year old trees being "cut down." Done as this was under Mr. Cameron's advice, the presumption is that growth in Maskeliya is rapid beyond Indian experience.

TEA IN CHINA.

Sir,—The interesting article on the manufacture and sale of Indian tea, in *The Times* of March 24, contains the very practical suggestion for the development of that important industry that the Chinese system of tea-hongs should be established in the principal centres of cultivation.

Having had exceptional opportunities of studying the whole Chinese economy of tea growing, picking, sorting, firing, and packing, it is possible that my experience may be of some use to those who may wish to interest themselves in this subject.

In the year 1861, when the Yangtse-kiang had just been opened under Lord Elgin's Treaty and the extensive tea-growing regions of Hupeh and Hunan were made accessible by that great water-route, I was sent by my employers at the opening of the season to superintend the purchase and manufacture of the first pickings of the tea, under the impression, not always justified by experience, that the nearer one could approach the source of supply the cheaper one could buy. Europeans had begun to settle in Hankow so soon to become a great inland seaport, and there my modest expedition was equipped. After three days and nights of slow but comfortable travel in an empty tea junk I landed at a point on the river 100 miles above Hankow, called Sz'ting, my

most lively recollection of which is the unspeakable swarm of mosquitoes, which however, entirely succumbed to fumes of chemically-prepared touchwood. The journey thence to Yung Lan-tung was over a most interesting mountain track, the path consisting of steps cut out of a precipitous wall of a rock, round which the coolies who carried the chairs in which we rode stepped like cats, gripping the rock with their toes, in places so narrow that their bodies only could pass when turned sideways. I doubt if I should have dared to walk on my own legs along such a track, and it was not without considerable trepidation that I allowed myself to be carried on the shoulders of other men who far from sympathising with my nervousness, kept up a loud discussion with each other at the most critical turns as to how much money they were to receive and how they would spend it.

Yung Lan-tung is a town of tea-hongs in a valley surrounded by tea plantations on the hill-sides. The first packing having been finished before my arrival, the sun-dried leaves were being brought into the hongs in baskets for sale. There is always enough free selling to make a market, but a large proportion of the crop is bespoken by the hong merchants, who make advances to the growers. A tea hong is a large solid brick building on the typical Chinese plan, court within court, covering ground measuring 500ft. by 200ft.

The tea buying is carried on very rapidly. The buyer stands on a raised platform, the sellers in the large open court in front. Each seller hands up a sample of his leaf on a small wicker tray for inspection, when the buyer, without a moment's hesitation, fixes the price, and writes it on a slip of paper, which is handed to the seller, who is equally prompt in accepting or rejecting the price offered, and there is no chaffering, time being too precious. If the price be accepted, the leaf is at once carried into the hong, weighed, and the money paid on the nail. There is always keen competition among the buying hongs, and the growers are thus secured a full market price. after the buying for the day is over, the qualities are sorted out, the leaves are slightly fired, and then packed away, as tightly as hay in a stack, in dark stalls in the interior of the hong, where the tea is left till fermentation commences. It is then put into the hands of the pickers, women and girls, each of whom receives one katty (equal to 1⅓ lb.) at a time, from which they pick out the brown leaves and stalks. The leaf is then winnowed to throw the dust off. The fresh leaves which are left are gathered together and fired, which is the most important process of all, as the appearance, character, and flavour of all depend on the skill and are of the firing. There manager sits up all night watching his hundreds of baskets of tea slowly baking over charcoal fires. When done to a turn the charcoal pans are suddenly removed and the tea allowed to cool. It is then ready to be packed into the familiar lead-lined chests for shipment to England. A "chop," or one firing of tea, varies from 600 to 800 chests. The chests are made to order, of uniform size and weight, and the tea is not weighed, but carefully measured into the chests. An impression used to prevail that the tea was all picked with chop-sticks, but I found that it was only the samples which are made up for the sale of the tea that were put through this process of selection ; and much labour and sorrow it entails on both buyer and seller in the rejection of chops of tea for being inferior to sample.

Not having visited the Indian tea district myself, I should not like to say how much of the above-described Chinese practice might profitably be adopted by the Indian planters. But as in the course of my business as a tea dealer both Indian and Chinese tea pass daily through my hands, I should judge from the practical results of the Indian process that the Indian planter has little to learn from the Chinese in respect of the firing or manufacture of the leaf. There would seem, however, to be obvious advantages in separating the growing from the manufacturing and packing, carrying on the latter processes on a larger and more uniform scale and at a very much less cost than is possible where each small garden has to keep up its own separate establishment.—I am, Sir, yours truly,

7 and 8, Idol-lane, E.C. JAMES INNES.

—London *Times*.

[The above is interesting, but there is a good deal which requires explanation. If we understand aright, the tea leaf purchased at the hongs has been rolled and sundried (!) by the growers. It is then partially sorted, slightly fired and closely packed in dark stalls where it ferments ! It is then apparently again sorted and sifted, and there is a final firing before packing. But Mr. Innes confuses the matter by stating that it is the "fresh leaves which are left" that are gathered together and fired ! India and Ceylon tea is, when gathered, spread to wither, it is then rolled, put under blankets to ferment and then fired. The sifting and sorting follow and a final firing before packing.—ED.]

YARROW CINCHONA LEDGERS.

We now publish the promised report on the sale of Yarrow ledger bark to Messrs. J. M. Robertson & Co., agents for the great Milan quinine manufactory. The sale is a very satisfactory one and a good test of what the richer barks will fetch in the market :—

Colombo, 4th May 1883.

W. F. Laurie, Esq., Yarrow.—Dear Sir,—Mr. Symons analyzed your small consignment of Ledgeriana bark with the following results :—

Stem quill	5·77	Sulphate of Quinine.
Chips and branch	5·18	do

We sold the quill R2·42 per lb. and the chips and branch R1·75 per lb. being at the rate of 42 cents per unit of quinine. The buyers, who act as agents for the principal buyers of cinchona in this market, informed us that they could not pay more, as they only had limits for bark yielding up to 5 per cent quinine, and the parcel was too small to induce them to exceed their limits. They have, however, written to their principals for limits for bark yielding 5 per cent quinine and upwards.—We are, dear sir, yours faithfully, SOMERVILLE & Co.

THE PROBABILITY OF THE BARK OF *C. LEDGERIANA* DETERIORATING AFTER A CERTAIN AGE: SPLENDID BARK FROM YARROW LEDGERS.

In copying the following account of the bark of Ledgeriana trees grown at Coonoor, from the *Madras Mail*, we would attract attention to the fact noted by the writer that the bark of a tree seventeen years old gave less quinine and more cinchonidine than the bark of younger trees. But caution should be exercised in drawing conclusions. Mr. Broughton laid down the general proposition that the bark of the cinchonas deteriorated after ten years of age, but Dr. Trimen shewed recently the grand results obtained from an old succirubra tree. Our own opinion is that trees of all kinds, even the best. will be found to vary, and it is encouraging to learn that the progeny of Ledger plants yielding only 7½ per cent gave 14 per cent of quinine. And this reminds us of a couple of magnificent specimens of Yarrow Ledger bark which have been sent to us with a re-

commendation to taste the bitterness. All we can say is that finer bark we never saw. In colour it looks like old succirubra bark, but in thickness and quality it is evidently far and away beyond any succirubra bark ever grown.

Mr. W. Lee Kirby, of Brooklands estate, Coonoor, writes :—"As many of your readers are interested in the cultivation of cinchona on the Nilgiries and elsewhere, the following analysis of the barks of 39 trees just received from Dr. B. H. Paul, of London, may prove of some interest to them, more so as this analysis unquestionably shows that, after a certain age, which one may conclude to be the eleventh or twelfth year of growth, the sulphate of quinine which makes the ledgeriana variety so valuable, gradually disappears, and dissolves into inferior sulphates and alkaloids. I refer particularly to tree Z, in the list given below, as I have every reason to believe all the other trees, with the exception of those marked E. K., are plants raised from this tree Z, planted in 1866, and raised from the original seed procured by Mr. Ledger from Peru in June 1865. The foliage and bark of the tree itself testify in every minute particular to its true type. The trees E. R. are also of the same age, raised from Mr. Ledger's seed, but of a different character, and here is noticed also how the sulphate of quinine is dissolving into cinchonine. A question of great importance to be solved is, will the renewed bark of old trees give the amount of sulphate of quinine one might assume the original bark of these sixteen year old trees would have yielded at the age when their barks contained the most sulphate of quinine? I have proved that even suckers hardly an inch in circumference growing out of a tree still standing contain a very extraordinary proportion of quinine sulphate to the tree from which the sucker comes, as can be seen in the tree marked S., where the bark from the small shoots gives an analysis of 5·49 per cent against the bark of the tree itself, analyzed, 8·83 per cent of sulphate of quinine. These trees being entirely isolated from any other varieties of cinchona may possibly yield seed which will produce a yet more valuable quinine-producing offspring, as a friend of mine, and one of the oldest cinchona planters in Java, writes me, he has obtained from a parent tree, the bark of which only analyzed 7½ per cent of sulphate of quinine, progeny which has yielded as high as 14 per cent of quinine. We may therefore still hope to see, with good cultivation and a suitable climate, together with a judicious selection of seed or seedlings of undoubted origin, "Ledger" bark selling at half a guinea per pound even when the price of quinine has fallen 25 per cent below its present market value :—

THE BREADFRUIT TREE (*ARTOCARPUS INCISA*, LINN.).

Whilst there seems a sort of mania abroad at present for raking up and discussing all sorts of plants producing valuable or imaginary products, reminding us of the old herbalists, there are several useful plants which seem to be neglected, and, as far as Ceylon is concerned, we may instance the breadfruit tree, introduced to the island early in this century, and of which we have only one variety, and that a very inferior one, bearing only once or twice a year. No attempt has yet been made by Government or private individuals to introduce better varieties, several of which are known to exist in the South Sea Islands, unless it be by the Hon. F. M. Mackwood, whose attempt to introduce good varieties failed in consequence of the plants having died on their way to Ceylon, from want of a proper mode of sending them, no doubt. The failure of the unfortunate Captain Bligh's first attempt to introduce the breadfruit tree from the South Seas to the West Indies, in the "Bounty," is well-known, but in January 1793 he arrived in the West Indies in His Majesty's ship "Providence," having on board breadfruit trees, and a vast number of other choice and curious plants. The breadfruit of Dampier, Anson, Cook, Allis and others, which is a native of the Moluccas and the South Sea Islands, is likely to have been introduced to Ceylon by the Portuguese or Dutch before 1793, and is known to the natives as the *rata* (foreign) *del*. A close ally of the real breadfruit, the *del*, *Artocarpus nobilis*, Thw. and one with a small fruit, the *Artocarpus Lakoocha*, Rox., are natives of Ceylon, whilst the jak-tree, *Artocarpus integrifolia*, Linn., is a doubtful native.

When the Rev. W. Ellis, the accomplished author of *Polynesian Researches*, visited Ceylon in 1854 or 1855 he mentioned the fact that we had only one variety of the foreign breadfruit tree in the island, and that a very inferior one : this fact was mentioned by Mr. W. Ferguson in his footnote to Cameron's *Gardening in Ceylon*, in Ferguson's *Ceylon Directory* for 1863, p. 218, and has several times been alluded to in these pages since, and though they seem to have in the South Seas many varieties of the breadfruit with large and small fruits, and of several qualities, some of them in fruit at all seasons, just as we have varieties of the mangoes in Ceylon, nevertheless here we are in 1883 without any regular attempt, except the one referred to, to introduce better varieties of the breadfruit into Ceylon. The late Mr. Dyke, Government Agent of the Northern Province, for many years kept getting supplies of plants from the Western Province to be distributed in Jaffna of this valuable vegetable. Our Ceylon variety bears no seeds, but in the South Seas and West Indies they seem to have seed-bearing ones called *Nucifera* or breadnut tree, and seedless ones, *Apyrena* or breadfruit tree.

In addition to the extracts we give from Bennett's *Gatherings of a Naturalist*, who gives a list of no less than 24 varieties of the breadfruit, and Horne's *Fiji*, we would refer our readers for further information to Ellis's *Polynesian Researches*, vol. 1, pp. 39-43, Williams's *Enterprize in the South Sea Islands*, pp. 421-23, for most interesting facts on the different kinds and uses of the breadfruit tree. We extract as follows :—

Next to the above-mentioned food plants comes the breadfruit (*Artocarpus incisa*) which is a most useful as well as a highly ornamental tree. It sometimes attains a height of 50 feet, but the average is from 30 to 40 feet. In general its trunk will measure about 15 feet to the first branches, with a girth of 3 to 4 feet. It is a horizontal branching tree, with a cone-shaped head. The leaves of the young trees are sometimes 2 feet in length, and from 12 to 15 inches in width. Those of the older trees are little more than half that size.

They are covered with rough hairs, which makes them disagreeable to the touch. Some of the varieties have leaves deeply lobed, and those of some others are almost entire The fruit of some of these varieties weighs as much as 9 lb., that of others does not exceed 1 or 2 lb., and 4 or 5 pounds may be reckoned the average weight throughout the group; They are in general cone-shaped, flattened at the base, or spheroid. The quality of some of them is excellent, dry and mealy like a potato; that of others is watery and insipid. They are either baked or boiled, and eaten alone, or with pork or fish. Sometimes they are made into puddings, or buried under ground, and made into a *Mauhrai*, *i.e.*, native bread. At all periods of the year there are some of the varieties in fruit, but the fruit is most abundant from the middle of February to the middle of April. In some of the native towns the trees are abundant, and groups of 20 or more, may frequently be seen scattered over land which had been cultivated. Large numbers of trees were destroyed in the wars that constantly occurred between different tribes,—the first acts of an invading force being to destroy food plants and fruit-bearing trees of the tribe invaded.

One or more of the varieties of the bread-fruit bear seeds, but the most of them are barren. It is doubtful whether these seed-bearing trees are varieties of the *Artocarpus incisa*, or if they do not form another species of the same genus. The wood of the bread-fruit is used for some purposes by the Fijians, but it is not so good as that of "Jack" (*Artocarpus integrifolia*) or the *artocarpus hirsuta*. It is soft, light brown, with parallel veins of a reddish colour. When wounded, the trees yield a large quantity of white sticky juice, which is used for caulking the seams of canoes. The tree is propagated by suckers attached to a portion of the root from which the sucker has sprung. The young trees grow rapidly, and in the third or fourth year after planting they reach a height of about 16 feet, and begin to bear fruit. They have a picturesque appearance peculiar to themselves, of which a minute description would convey a very indifferent idea.

The bread-fruit tree (*Artocarpus incisa*) is one of the valuable indigenous productions of the island of Tahiti; and as it bears at various periods in different parts of the island, the fruit can be procured during the whole year. There is also a variety with seeds, called by a distinct name, which I have seen at Erromanga (New Hebrides group), and it is also found at the Navigators' and Marquesas Islands. The *Artocarpus* delights in rich, moist, and sheltered situations, and is not found on elevated lands. The general name for the bread-fruit tree is *Maiore*; there are twenty-four varieties.* A white viscid juice is collected by incisions from the trunk, which is an excellent substitute for pitch. This tree attains the height of from 50 to 60, and a circumference of 6 feet. The timber is excellent and durable, and is used by the natives for building their vessels, as well as for other purposes; its colour is reddish-brown, becoming darker with age; the sap-wood is light yellow. Some of the native cloth (named *Hobuu* and *Aaone*) is manufactured from the bark of this tree, after undergoing the same preparation as the bark of the Auté, or Paper Mulberry (*Broussonetia papyrifera*): this latter plant is a shrub, from the inner bark of which the Polynesian islanders manufacture their primitive cloth: the Japanese are said to use it in the fabrication of paper.

* 1. *Paea.* This is a mountain bread-fruit: the fruit is long, of a large size, and very rough or tuberculated.
2. *Rare.* The fruit is round, with a bright epidermis.
3. *Maire.* One of the best kinds: it is a large and round fruit, with rather a smooth skin, and the leaves are more divided than in any of the other varieties.
4. *Rautia.* 5. *Buero.* 6. *Rammae.*
7. *Aravei.* A long fruit with smooth skin.
8. *Pehi.* 9. *Peiahuri.* 10. *Iatura.*
11. *Piipiia* 12. *Iofai.* 13. *Faara.*
14. *Opiha.* 15. *Ofatia.* 16. *Roru.*
17. *Oviri.* 18. *Otea.*
The fruits of these last-named eleven varieties are of large size.
19. *Pafara.* 20. *Afatu.* Both these bear small and round fruit.
21. *Tao.* 22. *Pafai.* 23. *Anuanu.*
24. *Maiore maohi* (the common bread-fruit).

COFFEE LEAF-DISEASE.

FINAL REPORT of the COMMITTEE appointed to inspect Mr. Schrottky's CARBOLIC TREATMENT FOR LEAF-DISEASE on Claverton, DIKOYA, CEYLON.

Summary of Operations Pursued.—Mr. Schrottky's system consisted firstly in dusting the trees with a pink carbolic powder twice at an interval of a week immediately after pruning. This was done in the presence of members of the Committee on 16th and 23rd April 1882, the weather on each occasion, and for some days after being most favorable for the best results claimed for the dusting process by Mr. Schrottky. This treatment was supplemented ten days later by what Mr. Schrottky terms his permanent system of evaporization. Measured quantities of a much more strongly carbolized powder were placed out in covered coconut shells, 36 feet apart, throughout the coffee. The powder was renewed fortnightly and stirred up twice in this interval, say from 3rd May to 10th November, when the supply provided for the experiments was exhausted.

2.—*Area Selected for Operation* and approved by Mr. Schrottky was a square block of 100 acres 10 year old coffee bounded on the North by the Dikoya river, on the south and west by Claverton coffee, 7 and 9 years old and on the east by Castlerea. This field as well as the two adjoining fields of Claverton coffee had all been manured similarly in July-August 1881, but only the 100 acres had been pruned previous to the experiments. The Superintendent's report to the Committee of 20th April 1882 stated that "leaf-disease had been very virulent all over this coffee from the end of June to the middle of October in 1881 and caused great loss of crop during the earlier pickings. The central portions of it and the river faces which are intersected with mossy ravines were at all times of the year infected with the worst forms of the fungus and from the signs of leaf-disease then present it appeared likely to develop itself as fully in the same months of 1882."

3.—*Record of Observations Made by the Committee, Supplied by the Superintendent on the Spot.*—At the commencement of the experiments leaf-disease was apparent everywhere in in such a modified form as is usual in the district at this time of year (April): From May to July it spread very rapidly on the unpruned coffee, while on the pruned and treated 100 acres the disease was scarcely perceptible. At the end of June, when the committee reported progress, no more striking contrast could have been presented to the eye or a more conclusive proof in favor of the treatment been wished for, but for the one fact that the 100 acres had been pruned and the other coffee had not. There were however many minor circumstances such as the absence of fungus in distinct patches anywhere and especially where it had usually been most severe previously, to induce faith in the treatment. Also there was an eastern face with a good crop on it that had been only pruned lightly, which was very free from any symptom of disease, while the unpruned coffee on the same slope higher up was completely eaten up with it. On the whole it seemed impossible to attribute the good results obtained to *pruning alone*, but, owing to the difficulty of making a fair comparison, it was decided to compare the Claverton 100 acres later on with a field of Castlerea coffee that had been pruned at the same time. This was not done till October, previous to which a very marked attack of leaf-disease had been reported on the Castlerea field in July without any corresponding attack having been noted on Claverton. The Committee made a careful inspection of both fields on 12th October, and the balance of opinion was strongly in favor of there having been much less fall of leaf previously on Claverton than on Castlerea, while the appearance of the Claverton coffee left little to be desired in point of color and general freedom from disease. It was, however, decided that, as the setting of crop was the real result looked for, no opinion should be hazarded until after the blossoming season. In November and December a very heavy fall of leaf was reported from Claverton, having apparently no connection whatever with leaf-disease, although far in excess of the ordinary fall of leaf which was occurring on neighbouring estates at the same time. This abnormal loss of green leaf favors the belief that some change has come over the character of the wood itself and that

(perhaps from the weakening of disease) trees are unable to carry their leaves to maturity, as should be the case with naturally healthy coffee.

4.—*Crop gathered on the 100 acres* was 750 bushels of parchment. Three-fourths of this was picked off the upper 45 acres, and on two small faces bearing heavily was well carried without manure, and the coffee is now looking well.

5.—*Appearance of Wood with reference to the Setting of Blossom.*—The Committee made their final visit of inspection to examine the result of blossoms on the 24th instant, and were of opinion that no difference could be traced between the setting of the blossom on the Calverton 100 acres and other coffee in the neighbourhood. They were again impressed with the good appearance of the coffee which did not look as if it had suffered from leaf-disease through the discontinuance of the treatment for now nearly five months.

6.—*Apparent Results of the Experiments* must still remain very much a matter of opinion. It must be admitted that the coffee treated has been unusually exempt from leaf-disease for a period of a year and the comparison with other coffee pruned at the same time would induce the belief that the treatment has to some extent been efficacious. On the other hand it is well known that the evaporization of carbolic gas, which Mr. Schrottky calls his permanent system, has, wherever else attempted, been declared a failure, nor is there anything in the history of the Claverton experiments to lead to the conclusion that it has been necessarily a success there. These is much better ground for thinking that the dusting process, aided by favorable weather, was at the time very effectual, and it is quite possible that the disease spores above the surface of the ground were sufficiently destroyed to prevent it making head again for a considerable period.

7. *Practical Deductions from the Experiments.*—The Committee are unanimously of opinion that carbolic acid, as hitherto applied, cannot be regarded as supplying any practical cure for leaf-disease. The dusting process might at times be applied with as successful results as certainly seemed to have attended its use on Claverton, but it would far more often be accompanied with less favorable weather, in which case an outlay of from R10 to R15 per acre might be completely thrown away. The Committee are of opinion that it would be far more economical to spend money on pruning or manure than on any topical treatment that has yet been suggested.

GEO. GREIG, W. TAYLOR, GILES F. WALKER, F. G. A. LANE, E. H. SKRINE.

REMARKS ON SOME MEDICINAL PLANTS OF CEYLON.

BY W. C. ONDAATJE, F. L. S., *Colonial Surgeon of Ceylon.*

It is well known that several Indian drugs have been incorporated into the British Pharmacopœia, which have added to the number of remedial agents, thus conferring no small advantage on the medical profession, and the publication of the Pharmacopœia of India has conferred an incalculable benefit on the medical practitioner in the East, but still there are many medicinal plants of the colonies and India which deserve a scientific examination.

The public revenue of the colonies is applied to many useful purposes for promoting the general welfare of the people. I believe that if a sum of money were voted annually to be expended in carrying out chemical examination of indigenous drugs and other products by competent persons in this country, all expenditure would be well repaid by the advantages reaped in the saving of Government expenses for medicines and in the demand created for native products.

It is a matter of great importance to the millions in the East, and in fact to the whole community, that they be enabled to avail themselves of efficient substitutes for many official drugs which our colonies supply.

I may here mention that the annual cost of drugs for the use of the public service of Ceylon forms a considerable item. The natives are now more largely availing themselves of European medical practice, since the extension of Government hospitals and dispensaries, and consequently an increasing expenditure under this head cannot be avoided without detriment to the best interests of the population.

The necessity for adopting such a measure as I have suggested will be apparent to those who have studied Indian drugs

The natives of the East have attributed imaginary properties to many plants and drugs, and much that is absurd is mixed up with much that is valuable.

While clinical observations in hospitals and medical colleges are of much importance to ascertain the therapeutic action, chemical examination will perfect the knowledge thus obtained, and will, with the aid of pharmacy, show the best mode of preparation and administration, and no institution can more efficiently carry out this work than the Pharmaceutical Society of Great Britain.

I will now proceed to make a few brief remarks on some medicinal plants which I brought with me from Ceylon.

1. *Randia dumetorum*, Lam.—The seeds of this tree are used by the natives of Ceylon and India as a reliable agent in producing emesis.

I am not aware that any chemical examination has been made to detect the active principle.

It belongs to the same family (Cinchonaceæ) as *Cephelis Ipecacuanha*, and it would be important to determine if it contains emetine, more particularly since an allied species, *R. uliginosa* is, according to Dr. Dymock, used in India as a remedy for dysentery. This species is also indigenous in Ceylon. The bark of *R. dumetorum* also possesses the same qualities.

I have seen the powdered seeds used with as good effect as ipecacuanha in doses of 5 to 10 grains. If analysis should prove *Randia* to possess the same active principle as ipecacuanha, a great saving might be effected by its substitution for the more expensive Brazilian drug.

Some weeks ago I had the pleasure of presenting a small quantity of the fruit to your Museum.

2. *Sethia acuminata*, Arn.—This is a remedy much used by the Sinhalese as a vermifuge. The part used is the leaves, the juice of the leaves being mixed with sugar and castor oil, or with the powder of the leaves. The leaves are easily powdered when dried.

Professor Bentley notices its vermifuge properties in his 'Manual of Botany.'

Dr. Thwaites, in his 'Enumeratio Plantarum Zeylaniæ,' also refers to it. He says "the Sinhalese attach much value to this plant as an anthelminthic for children, giving the juice expressed from the fresh leaves." It is chiefly used for expelling round worm and possesses the advantage of not having a disagreeable taste. The powder is used in the dose of 10 to 15 grains.

I presented a small quantity of the leaves and a flowering specimen of the plant to your Museum.

3. *Coscinium fenestratum*, Colebr.—Many years ago, while using it as a tonic, I found by experiment that it possessed *antiseptic* properties, to which I beg to invite your attention.

I found that pieces of beef immersed in an infusion of the stem were preserved for several weeks. I am unable to give more details, as my notes made in Ceylon are not at hand.

I also used in Ceylon a weak infusion of the stem as a lotion of foul ulcers with great success.

I believe the plant has already been subjected to chemical analysis in this country and contains the active principle berberia.

It has been used also as a yellow dye. As this root has recently been imported in quantity into England it could easily be obtained, and an examination of the cause of its antiseptic properties seems desirable.

4. *Vateria Indica*, L.—Some of the bark of the tree I have presented to your Museum. The natives used it daily to arrest the alchoolic fermentation of the juice of the jaggery palm, *Caryota urens*, which is a favourite beverage with the natives. This property of preventing fermentation might, I think, be turned to account in some of the great manufacturing industries, if not in medicine, and I trust the bark may be thought deserving of chemical investigation by some members of your Society.

5. *Semecarpus Gardneri*, Thw.—The black resin yielded by this tree, although not possessing medicinal properties, may be of some interest in the arts.

I have presented to the Museum some of the resin.

The resin is hard, breaks with a smooth fracture, burns with a bright flame, is soluble in turpentine, and adheres strongly to wood and metal. It is free from acridity.

The formula for using the resin as a varnish is as follows:—

To a saturated solution of *Vateria Indica* resin in oil of turpentine, add by degrees pieces of black resin, and

put it into a bottle and shake it well until the whole is dissolved, then apply it to wood or metal, which will give a varnish of great lustre and beauty. The resin should be first melted and strained through coarse calico or a sieve, to free it from impurities.

6. *Vernonia anthelmintica*, Willd.—This plant is cultivated by the Sinhalese and is in great repute as a remedy, which is indicated by its name.

The seeds are black, of a bitter and nauseous taste are easily procured from bazaars and are commonly used by the village people for expelling the ascaris lumbricoides and act as a vermicide.

The dose of the powdered seed to an adult is from ½ to 1 drachm.

The native physicians prescribe it generally as a tonic in the shape of an infusion.

The Sinhalese name is *sanne nayan* and the Tamil name *kadoseragam*.

European practitioners in India, from personal observations, confirm the truth of the above statement.

7. *Alstonia scholaris*, R. Br.—In 1865 I forwarded to England, to my friend and correspondent, Mr. P. L. Simmonds, the Editor of the *Technologist*, specimens of a kind of caoutchouc, as a substitute for gutta-percha.

The following information supplied by me appeared in that periodical for August 1865:—

"Another substitute for gutta-percha, the milky juice of the *Alstonia scholaris*, a tree belonging to the natural order Apocyneæ, has been forwarded from Ceylon by Mr. Ondaatje; it is stated to possess the same properties and to be workable as gutta-percha. It readily softens when plunged in boiling water, is soluble in turpentine and chloroform, receives and retains impressions permanently, and is adapted for seals to documents."

The bark of this tree is thick and spongy. Its properties as a medicinal agent are fully described in the Pharmacopœia of India*.

8. *Acorus Calamus*, Linn.—The well-known sweet flag I merely notice as an anthelmintic, which property is not included in the Indian Pharmacopœia.

An infusion of the rhizome or root stock given to young children acts effectually, as I have seen many such cases treated among the natives.

THE BULKING OF INDIAN TEAS.

TO THE EDITOR OF THE "HOME AND COLONIAL MAIL."

SIR,—There appeared in the London *Times* of the 24th ult. under the above heading, an article "From a Correspondent," in which the writer professed to examine the grievances which the Indian tea planters have through the Indian Tea Districts Association, lately laid before the Secretary of State for India. This correspondent offered certain criticisms on the points referred to in our memorial and on the situation generally. I trust, by your courtesy, to be allowed to reply to these remarks. In the first place, the correspondent admits that the grievances in question are "not wholly groundless," though he adds "the remedy should probably be sought in another direction," and that the present treatment of Indian tea "inflicts a serious burden on the trade, not only through the expense, but *the destruction of the chests and their contents.*" The only difference between us, then, is the direction in which we are to look for a remedy. From the evidence afforded by the correspondent's letter, it is clear that he is practically unacquainted with the conditions under which the great Indian tea industry is carried on. He has also misunderstood and incorrectly set forth the planters' case in affirming that "what the planters claim is that one or two chests only out of a 'break' shall be opened, and the tare so found apply to the whole." The sole *burden of the planters' prayer* is that the tea shall be weighed, and the tare—that is to say, the weight of the empty package, whether box or chest—shall be disregarded. All the buyer demands is that the tea in a given number of packages shall be of even quality and ascertained weight. Neither the one or the other has hitherto commanded the attention of managers generally for the simple reason that while it is by no means difficult to procure woods suitable for the construction of cases that will serve the essential purpose of preserving the teas in a sound condition till they reach the hands of the retail dealer has been found difficult, costly, and uncertain, to construct these covering shells so as to ensure an even tare weight on arrival in London, *i. e.*, that the cases when *weighed empty* shall be found of uniform weight. This being so, the plan followed in the case of China teas of finding an average weight of the break or chop by taring a few test chests, fails to be applicable to Indian teas, and the whole of the chests have to be emptied of their contents, and *each* tared separately. The teas are then bulked and replaced in the cases, the importer getting credit for the quantity actually found irrespective of the Indian weights. Thus bulking and exact weighment in India are rendered practically useless unless the third condition of even weight in the empty cases is secured; hence the appeal of the planters and importers that this vexatious and uncertain factor should be replaced by the more intelligible and exact method of weighing the tea itself in a certain proportion, say from 5 to 10 per cent. if found necessary, of test chests to determine the average weight of the break.* Upon the adoption of this simple change of usage hangs the solution of the question whether bulking in India shall become the rule instead of the exception, and the teas be preserved from the deteriorating treatment they are now subjected to in the London warehouses. The advice given to "take a leaf out of the Chinese book" evidently implies a complete misapprehension of the difference in the working conditions of the two countries, a difference on which mainly depends the superiority of Indian over China tea. In China the cultivation is carried on in a thickly populated country by villagers, each of whom has his little patch of tea, and it obviously suits his purpose better to dispose of the produce, whether green leaves or crudely prepared tea, to a collector possessing the means and appliances for completing the manufacture on a large scale. In India, on the contrary, the cultivation of tea is almost entirely in the hands of Europeans. The gardens or plantations are not individually small as is stated, but consist of blocks ranging from hundreds to thousands of acres in extent. The different estates, however, are frequently widely separated, rendering the adoption of the Chinese system of "hongs" utterly impracticable even if it were desirable. Naturally, therefore, each individual estate has to provide its own "plant" in the shape of rolling and sorting machinery, buildings, &c. Many estates produce yearly 500,000 lb. of tea, several make 1,000,000 lb., while the famous old Assam Company turns out 2,500,000 lb. per annum. The distinct flavour and characteristics of different marks of Indian tea are due to the varying soils and methods of treatment. Were it possible to follow the advice of a correspondent, and blend the teas of all the Indian gardens, a result would be obtained such as would follow the mixing of all the wines of a vine growing district—a dull, undesirable uniformity.

Indian tea planters understand their business thoroughly, and desire to retain the high reputation they have gained for their produce. All they ask is that they shall not be hampered by unnecessary and vexatious trade restrictions.—I am, &c.,

ERNEST TYE, Secretary.

* Here is the whole heart of the matter. Indian and Ceylon planters cannot secure boxes of precisely similar weight, but surely, if 5 or 10 boxes out of 100 gave a certain hweigof tea, the customers and purchasers might well be asfiedtis to take the average.—ED.

CATALOGUE OF SPECIMENS OF CINCHONA BARK WITH ILLUSTRATIVE BOTANICAL SPECIMENS,

forwarded through Her Majesty's Secretary of State for India for the Pharmaceutical Society for Great Britain. (Furnished through Dr. Bidie.)

(From the "Pharmaceutical Journal.")

REMARKS.—*a*. This is the C. Uritusinga, type of Pavon. *b*. C. Uritusinga, Pavon type. *c*. C. Condaminea, How. variety. *d*. do How. type. *e*. These botanical specimens and also the bark were taken from coppice shoots. *f*. The bark belonging to this specimen is renewed, after the tree had been subjected to the Java shaving process. In this the outer cellular portion is shaved or pared off, the inner vascular layer being left intact. *g*. Bark covered externally with a thick corky layer, and very peculiar, of officinalis type but undetermined species. *h*. This is the C. Condaminea type of How. *i*. Large leafed or C. Uritusinga, Pavon type. *j*. This is the No. 1 form of C. Angustifolia, How., according to the estate nomenclature. *k*. This is the No. 2 variety, in the estate nomenclature, of the variety C. angustifolia, How. *l*. This species was discovered by Hasskarl, cultivated on a large scale in Java and found to be worthless. From Java it was introduced into India, but fortunately its culture here never went beyond the stage of an experiment. *m*. This plant was said by Cross, on his recent visit to the Nilgiris, to be the *C. crispa* of which he sent seeds from the Loxa Mountains. That it came from Loxa there is no doubt, as the few specimens of it on the estate of Dodabetta are growing amongst the "crown" barks introduced from that region. It differs, however, very much from the *C. crispa* of Tafalla, which belongs to the *C. officinalis* group of Weddell. In general appearance it is more nearly allied to Weddell's section *Pahudianæ*. Its bark is also very peculiar, in fact unique. *n*. This form of the *C. Calisaya* grows to a considerable size and has bright green shining leaves, some of which measure from 6 to 7 inches in length by 3½ to 4 inches in width. Flowers pink, very sweetly scented. *o*. This plant approaches the *Boliviana* form of Weddell, but the *Calisayas* are most variable.

At a meeting of the Society, Mr. Holmes called attention to various specimens of Indian bark which had been forwarded under the instructions of the Indian Government by Surgeon-Major Bidie, the Superintendent of the Museum at Madras. A descriptive catalogue of the barks, and of the Herbarium specimens accompanying them, is printed on pp. 821, 822. Mr, Holmes said that the bark were accompanied by excellent specimens of the plants themselves, representing the flower, the leaf, and the fruit, the Herbarium specimens being labelled with numbers corresponding to the numbers of the barks. The specimens had been prepared with the greatest care, and full details had been given in each case, both of the plant and of the bark. This was one of the most valuable collections of Indian barks which had ever been sent to this country. Great credit was due to the gentleman who had superintended the collection of these specimens. It would be possible in the future for any person who wanted to identify the bark which he was using to do so by comparing it with the Museum specimens. Two of the specimens were very interesting from a botanical point of view as showing that the cinchonas, like the elms and maples of England, sometimes produced a bark which was excessively corky. The cork in some of these barks varied from ¼ inch to ½ inch in thickness. There was also on the table a specimen of *Manilla Elemi* presented by Messrs. Evans, Lescher and Webb. It was imported in a new kind of packing, which he had never seen before. There was also a specimen of crude and refined ozokerit and an elastic bitumen from Castleton, in Derbyshire, somewhat approaching the coorongite of Australia.

The President said that the members of the Society would better appreciate the very complete catalogue of the specimens which had been sent with the collection of barks when they were able to read it. The Council of the Society had already expressed its thanks officially to the Government of India for its courtesy in passing on to the proper authorities the request of the Society to be furnished with these specimens. They had been collected and arranged under the personal superintendence of Surgeon-Major Bidie. If had not been for Surgeon-Major Bidie's zeal, probably the Society would not have been so successful in getting a complete collection, and certainly not so successful in getting such excellent botanical specimens. Their thanks were eminently due to him and the officials of the Government for their courtesy.

LEAF-DISEASE IN NETHERLANDS INDIA is evidently pursuing the same disastrous course as in the British East Indian possessions, as witness the following paragraph of Netherlands India news in the *Strait's Times*: —By last advices, leaf-disease had appeared on many estates in the neighbourhood of Samrang. Trees in hundreds have been thereby rendered leafless, no remedy apparently availing.

"TAPIOCA AND ARROWROOT."—A correspondent writes:—"Allow me to thank your Colombo correspondent for his valuable information as to boiling tapioca. It isn't likely I should eat it uncooked, but it isn't necessary to boil it at all. Baking answers the purpose equally well. For your correspondent's information, allow me to say my grand-mother used to tell me when a child that uncooked potatoes contained poison, and since then I have learned that many other esculent roots contain poison, but when subjected to either a dry or moist heat, the poison is expelled." Mr. J. W. Home informs us that he is prepared to supply 100 tons of tapioca per annum at 3d per lb.; but even at this low rate there is no local demand worth speaking of, and yet surely, in these "hard times," tapioca at 3d per lb., ought to be a famous article of diet in families with children.

MYSORE, April 21st.—Good prospects for cardamoms here, if we get April rains. But they have not come as yet. Why do not Ceylon fellows advertize in the *Ceylon Weekly Observer* or the *Tropical Agriculturist* cinchona seed. Two men do it, but where are the rest? We want variety to choose from. Narrow ledgers germinated beautifully common method. So a beginning in cinchona has been made. Queer climate. Been seedy for a month and-a-half. Will get used to it in time. Could give more hints on pepper and cardamoms, but am tongue-tied. Indian planters are not so free with information as Ceylon men. Witness Dobree with his startling pictures. He should have been an artist. Perhaps the engraver was of an independent turn. What knocks me up here is the kiln-like heat compared with the steamy heat of Ceylon. I'll do 30 miles a day in Ratnapura heat, when you reqire a horse here for ordinary work. They get their rain here all at once and heat ditto. Coorg coffee looking very pretty, but I sternly gaze on its charms, as cardamoms are what must be cultivated.

CANKER IN CINCHONA.—An absent proprietor writing by last mail from home says:—"I wish to give the ——— clearing another trial. Weakly and immature plants put out have, as far as I could judge, been the bane of cinchona planting. If plants in the nursery are not big and strong, why not leave them in the nursery where they can be carefully attended to, even though a season be lost, *i. e.* when good strong plants can be bought outside."

NUTMEGS.—The Macassar *Handelsblad* reports that the nutmeg crop this year in Menado is considerable. During the last five years, since a long continued drought in 1877, nutmeg cultivation has, however, sufferred greatly there from a disease, hitherto unknown, chiefly among the trees in bearing. On estates containing 4,000 to 5,000 nutmeg trees, about twenty or more of the latter die regularly every month. No remedy has yet been suggested for this disease, the roots being the part first affected. Their decay is followed by the trees withering away and dying more or less rapidly.—*Straits Times.*

TEA IN CEYLON.—The reason why the low-lying tea districts of this island, so favorable for the yield of tea, unlike those of India, are so favorable to health, is the fact of their exposure to healthy sea-breezes, which reaches them acrossan open, well-cultivated country. Yatiantota, Avisawella Dolosbage and the Morowa korle have none of them exhierating, bracing climates, yet they cannot be termed unhealthy for the reason abovenamed. In the Avisawella district, and those adjacent, tea flushes very nearly througout, the year, certainly in nine out of the twelve months, hnd during those nine months plucking rarely ceases. In the Morowa korle we believe a similar state of things prevails. After an interregnum of some years since King Coffee was deposed in that part of the island, it has been ascertained beyond a doubt that no more suitable district for tea exists in the country. The forcing qualities so detrimental to coffee production, and which were the cause of the abandonment of states on which much capital had been expended, are precisely those which go to make successful tea plantations. So undoubted has been the success attending the pioneer operations of tea planters in the Morowakorle, that the proprietor of a number of extensive estates on which coffee has proved a failure, has resolved, after an inspection of the land and under first-rate advice.*—"Ceylon Times."

A REMEDY FOR WHITE ANTS.—A report from the Commissioner for Railways to Mr. John Lackey, M.L.A., giving his experience of a very simple remedy for white ants, is as follows:—"It will be in your recollection that in May last year I brought under your attention, as Secretary for Public Works, that the ravages of the white ants in the bridges on the South-western Railway had been so severe as to justify the fear that a large expenditure would have to be incurred, if the evil could not be checked, in substituting iron for these wooden structures. You then suggested that a trial should be made of a mixture of arsenic and grease, and you stated your belief that not only would it prove to be a corrective, but that it would in a short time remove the cause of the mischief. It affords me pleasure to inform you that the application of this specific has been most efficacious. The engineer for existing lines has just furnished me with the report of the bridge inspector, who states that he has made experiments with it on fifteen culverts and five bridges, and in no case in which it has been applied is the white ant, which previously infested these structures, now to be seen. A large public saving has thus been effected."—*Queenslander.*

* Mr. Cameron's advice to Mr. Boustead on the Craven group of estates, we believe; and it is on the same "first-rate" advice that planters are encouraged to plant high up and to go on cultivating tea with he certainty of success even to 5,600 feet in Lindula, while the finest tea-garden Mr. Cameron has yet seen in Ceylon is close on 4,000 feet above sea-level.—ED.

SAN DOMINGO, in Laborie's time the great scene of coffee cultivation, exported only 1,260,800 lb. in 1881 and 340,500 lb. of cocoa. Nothing better could be expected of a country which has a revolution about every six months. Its chief exports are forest products which require but a slight exercise of skill and labour to collect. Amongst the exports are 354,000 lb. of divi-divi and 262,000 lb. "extract of logwood." If the dye principle can be extracted from logwood in St. Domingo, why is the inferior sappan wood sent from Ceylon in the block?

CINCHONA ROBUSTA.—Dr. Trimen advisedly recommended this name, because it left the question of distinct species or variety and that of hybrid, still open, although it was clear enough that Dr. Trimen agreed with the vast majority of planters in regarding the robust cinchona as a hybrid. But now, according to the London correspondent of a co-temporary, the great authority of Mr. John Eliot Howard is to be given against the hybrid theory. It would appear that he regards the tree as a variety of *C. succirubra.* This must be meant, because those who uphold the hybrid origin of the plant, also regard it as closely "allied" to the succirubra. Whatever Mr. Howard has to say on the subject will be received with the respect due to his age and his unrivalled experience.

THE TROPICAL AGRICULTURIST.—We have just received the April number of this useful publication, which has now been in existence for nearly two years. It is, as set forth on the title page, "a monthly record of information for planters of coffee, tea, cocoa, cinchona, sugar, rubber, palms, rice, and other products suited for cultivation in the tropics." It contains a reprint of editorials and correspondence on these subjects, which have appeared during the previous month in the *Ceylon Observer,* and also a collection of articles, reports, letters, &c., on the same and similar topics extracted from other journals and publications from all quarters of the world. Each number, consisting of 80 octavo pages forms a repertory of the latest information on subjects in question, which must be of the utmost value to planters in the tropics. We cordially recommend the work to those of our readers who take an interest in agricultural matters, and especially to all planters in Singapore and the Malay Peninsula. It is published at the *Ceylon Observer* Office, Colombo.—*Straits Times.*

CINCHONA LANDS in Jamaica are being bought up rapidly by officials, and others who have arrived here from Ceylon, India, and the United States. Complaints are however made that the Government sells land to men who buy purely on speculation to sell again when there is less to be had, and when a higher price can be obtained, the consequence is persons have to make roads through these lots to reach their own so that the lazy man profits by his laziness while the enterprising man has to make the road through his own property and his neighbour's besides. There is evidently need for some legislation in this repect for we believe the Government desire to be just in this matter. The land is sold for two shillings an acre on condition that one-sixth of it is cultivated in cinchona. If at the end of five years the purchaser has complied with the conditions of purchase, the land is then his for ever. The cost of clearing the land is £4 an acre and planting out £3. The total cost of clearing, planting and cultivating for five years is £30 the trees bear bark fit for cutting (by thinning) in four years and the purchaser then gets back all his outlay. Every year after the fourth is clear profit.—*Gall's Weekly News Letter.*

UNEQUAL DISTRIBUTION OF RAINFALL.

Our Australian friends who specially know what it is to suffer from drought, scarcity of pasturage, flocks and herds and destructive bush fires, will now learn from their fellow-colonists who have had such a striking and, we hope, refreshing experience in Ceylon, that it is quite possible to have too much even of such a good thing as rain. If we could only get mixed up with Australia and strike an average of moisture, we should no doubt feel that the arrangement would be an improvement on the existing state of things. We are reminded of the old doctor who said:—"No doubt when you knock your shin against a sharp object and are wincing from the pain, you think you could improve the human frame by placing the calves of the legs in front of the bones instead of behind." The true philosophy, however, without doubt, is that there are good and beneficent reasons for arrangements and phenomena which we cannot comprehend or only partially understand, especially in the case of the grand cosmic causes which influence rainfall. Even in Scinde, where rain sometimes does not fall for years, and where the average is only four inches, irrigation has converted portions into verdant gardens, and the same agency has been so successful in Australia, that explorers have ceased to regard as hopeless the central deserts of sand and stone and spinifex, now scenes of horrid and forbidding desolation, into which brave men have ventured only to die in the wild delirium of thirst. It seems more difficult to apply a remedy in such cases as that of Cherapunjee at the base of the Himalayas, the average annual rainfall of which is close on 600 inches (50 feet!), and where one year considerably over 800 inches fell, no less than 330 inches coming in the one month of July! Forty-eight inches or four feet of rain have been known to fall here in a few hours of one day. That is the climate truly to take the starch out of the stiff and to convert men of deficient backbone into limpness. Here, in Ceylon, our average range is from 30 inches at Mannar to 250 (280 were recorded one year) at Padupolla, under "the shadow of the Peak." Apart from the agencies which produce rain currents, there can be no doubt that the deposition of moisture is chiefly influenced by mountain ranges. As we go southwards from Colombo and nearer the hills, the rainfall becomes greater; the reverse process being observed as we go northwards and away from the influence of the mountains. Warm currents of air striking on the bases of mountains part with more and more of their moisture as they are forced upwards into the cold. But a point is reached where rainfall commences to decrease, and, at last, in the case of such high mountains as the Himalayas, it ceases altogether, and while the Khassia Hills at 4,000 feet elevation on the base of the Himalayas are deluged and send floods down into the valleys of Sylhet, the dwellers in the regions on the opposite side of the vast rampart sigh in vain for even a portion of the cloud treasures. No doubt experiences were different before the "grand abode of snow" was upheaved, and they will probably again change when Mount Everest, Kinchinjinga and Maha Devi cease to reign over "the upper crust of the globe." Meantime, all accumulated experience does but strengthen our conviction that the presence of forest depends on the presence of rainfall, and that the large number even of scientific men who believe they can by tree-planting convert arid regions into pluvial, are mistaken

In Scinde, for instance, we do not believe that any amount of "forestation" would sensibly increase the average rainfall of four inches, however much the action of irrigation and the presence of trees and plants may modify the climate otherwise. And so with the converse case: we feel confident that the denudation of forest for many miles around Cherapunjee would not lessen the average rainfall, though it would lead to the more rapid passage downwards of the waters and the more serious flooding of Sylhet. Here, in Ceylon the recorded figures shew that forest felling has not affected our rainfall a decimal: indeed, after half-a-century of coffee-planting our complaint is of too much and unseasonable rain; the very complaint which farmers in England make, after a thousand years of clearing and cropping. We can no more alter the great influences of nature by our puny operations on the surface of a few districts of the globe, than we can succeed in making one hair white or black, seize the ocean by its mane, or chain the winds which in obedience to a law which is now largely understood, go "circling about continually." We have before us as we write a map which shews rainfall with reference to the prevalence of forest trees in India, published in the *Indian Forester* to illustrate an able paper by Dr. Brandis on the distribution of forests in India, and also a somewhat similar map, coloured to shew the meteorology of India, and used by Sir Joseph Fayrer to illustrate a most interesting pamphlet on the Rainfall and Climate of India. Both maps teach the same lesson, that, as far as rainfall is concerned—the deposition of moisture—the climate of districts depends on their contiguity to or hosition in regard to the influence of mountain ranges. The rainiest region in India is on the western face of the Himalayas; the next rainiest is along "the Western Ghauts" of the Peninsula, from Bombay to Cape Comorin. In the *Indian Forester*'s map, white indicates the arid zone, under 15 inches of rainfall including the inland portions of Southern India and all that portion of India north of Delhi and from Kurrachee to Peshawur. Next comes the dry zone, (light green) from 15 to 30 inches, including a good deal of northern India and of the central portion of the Peninsula. The intermediate zone (light blue), 30 to 75 inches, includes the larger portion of India and Ceylon. The figures for rainfall in the case of our island are 72 inches against Colombo and 85 for Kandy. The true figures are:—

Colombo ... ... 86½ inches
Kandy ... ... 82 „

but portions of our island, Ambagamuwa for instance, ought to be coloured deep blue as in the moist zone above 75 inches. The Deodar (cedrus deodara) is refered to the arid zone under 15 inches, behind the Himalayas; sal (shorea robusta) and babul (acacia arabica) to the dry zone, 15 to 30 inches; caoutchouc (ficus elastica) and sandal (santalum album) to the intermediate zone, 30 to 75 inches; and teak (tectona grandis) to the moist zone, above 75 inches. The northern limit of this prince of timbers is marked by the course of the Irrawaddy. Mr. Vincent's report on our Ceylon forests is, we believe, to be accompanied by a carefully compiled map shewing rainfall and its influence on tree vegetation. But our chief interest at present centres in the south-west monsoon which, if it has not actually reached us, has certainly sent forward some its most forcible *avant-couriers* in the shape of rainstorms. Sir Joseph Fayrer in his able paper, shews the great influence of the physical peculiarities of a country, in determining the quantity, the distribution and the periods of the rainfall and he traces the origin of rain to the gaseous envelope of nitrogen and oxygen by which our globe is surrounded to a height of forty or fifty miles. Into this atmosphere rises watery vapour from the ocean, lakes, rivers, &c., until saturation takes place or until cold condenses the vapour into clouds, rain or dew. On the conditions which affect evaporation and condensation, rainfall de-

pends; but there is a constant circulation of moisture from the waters of the earth to the atmosphere and back again. "All the rivers run into the sea, yet the sea is not full; unto the place from whence the rivers come thither they return again." So that in all the variations a law prevails, and those who believe that "chance" or "forces" are alone at work, are not to be congratulated on their creed. Wherever there is water there is evaporation, but as heat is the great agent of evaporation, the process goes on most constantly and powerfully near the equator, and as the warm vapour-laden air ascends, it is replaced by constant currents from the poles, to be in their turn saturated, warmed and uplifted. Thus, there is a perpetual circulation, "making the equatorial rain-belt of great distillery of nature." Again to quote the old book:—"The wind goeth towards the south and turneth about into the north; it whirleth about continually, and the wind returneth again according to its circuits." Here is the foundation of "the law of storms" discovery. But there are disturbances of the regular laws in consequence of the greater mass of land in the northern hemisphere, and it is to perturbations hence resulting that the "MONSOONS" and their rain-laden winds are due. In regard to those phenomena, we quote from Sir Joseph Fayrer's pamphlet:—

"The great producers and distributors of rain in India, then are the monsoons or periodic seasonal winds. The term is of Arabic origin, from "Mausim," a season, and is applied to the great air-current that blows for one-half of the year northwards, carrying the moisture taken up from a vast extent of the Indian Ocean, extending from Africa to Malacca; whilst for the other half the year it blows from the opposite direction. The north-east monsoon corresponds to the north-east trade, and would be constant were it not for the counteracting influences which disturb the atmospheric equilibrium. Monsoons are not peculiar to India, but occur in other regions where there are similar distributions of land and water. The Indian monsoons are caused in the following manner:—About the commencement of April, when the whole surface of the continent of India becomes hotter than the sea, the rarified air rises, and is replaced by the comparatively cooler currents drawn in from, and laden with moisture taken up by evaporation from the Indian Ocean. This is the south-west monsoon, which, rising to higher regions, or, being intercepted by the mountain ranges, condenses, its moisture in rain on [the mountains of Ceylon Ed. C. O.] the Western Ghâts and on the coast of Aracan. Following a north-eastern course, it gradually loses its influence and its rain, as it approaches the northern limits of the continent. About October the winds are variable; there is a reversal of the current, which begins to blow southwards for the most part as a dry wind, till on the Coromandel coast it brings moisture from the Bay of Bengal, which falls as rain on the coast of the Carnatic and on the Eastern Ghats; whilst some parts of the South of India receive a certain amount of rain with each monsoon.

"This winter or north-east monsoon, which on land has a northerly or north-westerly direction, returns again as a south-westerly current in the upper regions of the atmosphere, having been heated in the south. It is sometimes called the anti-monsoon, appears to be felt in the Himalayas, and, descending in the North-West Provinces and Punjaub, brings their winter rains.

"The rainfall on the southern and western coasts is the heaviest; but there are many variations and peculiarities due to local conditions; elevated regions receiving almost a deluge, whilst some lower areas are very dry. All the conditions favourable to the condensation and fall of rain exist in certain localities, whilst the converse obtains in others."

AN ABORTIVE LIBERIAN COFFEE TREE.

On receiving Mr. Hadow's letter (on page 990), our first conclusion was that the isolated tree which never matured true fruits was uni-sexual. But after a conversation with Mr. Wm. Ferguson on the subject, and seeing the "leafy matter" in the interior of the apparently well-formed beans, we have no further doubt as to the cause of sterility. It is one to which individual trees of all species are liable, that of never being able to carry their fruits beyond the leaf stage. One of the most important and most pregnant discoveries made in botanical science was that which proved that bud, leaf, flower, fruit, thorn, branch and twig, were all but developments and modifications of one original principle in plant life. Why some plants should bear "nothing but leaves," others nothing but thorns, while others again throw their whole energies into flowers and fruits, we may not be able to understand; but we well know to our cost here in Ceylon that unfavourable weather may convert coffee blossom into coffee leaves. In that case, however, the transformation takes place before our eyes, and we are not, as in the case of Mr. Hadow's isolated tree, deceived into the belief that we are to gather a crop of good cherries containing well-formed beans. The beans in this case are just layers of undeveloped leaves. From the external appearance of the cherries no one would suspect this, but usually in such cases the pseudo-fruit puts on an abnormal appearance. For instance, we once saw a coconut which looked for all the world like a bunch of plantains, and Mr. W. Ferguson told us of a coconut he had received from the Messrs. Leechman which was a grotesque cross between fruit and leaf. We fear that in the case of the isolated Liberian coffee there is not the slightest hope of amendment by any possible treatment which can be applied, although we should be curious to learn the effect, if any, of attempting to fertilize the blossoms of this tree by pollen from the fruit-yielding Liberian bushes in the neighbourhood. It is an unfortunate chance that a tree, isolated, pruned, manured and forked as this one has been, should still resemble the barren fig-tree of the parable. But one further experiment might be tried. As roasted coffee leaves yield an infusion acceptable to some, the "leafy matter" might be roasted and ground and then brewed, so as to see whether after all the abortive fruits may not be good for something. If this is done, we should like to hear the verdict on the resulting beverage. Meantime the tree is a curiosity, and we have no doubt, Dr. Trimen would be glad to obtain cherries for examination and branches with flowers and fruits for his herbarium. Happily abortive Liberian coffee trees must be very rare, for this is the first which has been brought to our notice.

GENERAL PLANTING REPORT FOR THE HILLCOUNTRY OF CEYLON.

Kandy, 11th May 1883.

Sultry, steamy weather up to the 8th instant, when the S. W. suddenly put in an appearance. Rain, cloud and wind have combined to reduce the temperature, the former will help to swell out the coffee berries that we may expect for autumn, and planters will soon be able to judge pretty accurately of what the outturn should be.

Short, shorter, shortest.

Let us hope good prices may be realized as a slight make-up for short crops, and that "*M. plant-*

ation " may reach the three figures ere *A. D.* 1883 is extinct. The question may soon arise as to what has become of all the blossom which rejoiced so many hearts a short time ago. Query indeed! Some say rain, some say sun spoilt it, and some there are who delude themselves into the belief that it has—all set! and that they are going to pick a " bumper." The word "bumper" reminds one of the "good old times," when estates could afford to pay R2·25 curing charges; how is it that *such* charges are still *almost* the rule? Messrs. Baker & Hall advertize a reduction of 50 cents per cwt. on this sum, and surely it is time for struggling planters to make an effort and say to those princes of " ye sleepy hollows " : " *Reduce* your charges and give us a *better* average outturn for our parchment!" It *can* be done, and it should be done. Expenditure on everything else is cut down to the lowest and even mortgagees have been known to ease the interest, but our merchant princes grind out the uttermost farthing!!

Who is to be King, after the demise of our old friend " Arabica." This is a question that requires mature divination.

Tea and cinchona at present seem to be in the majority. Cocoa, however, has many and strong admirers, and undoubtedly gives a handsome return, but it will not cover the *thousands* of acres that the former is bound to do, nor will it suit many localities on account of its deadly enemy " wind". Tea will be the mainspring of our future, and we should try and do it all the justice we possibly can, as regards cultivation as well as manipulation. A *good* cup of tea is a thing to be *remembered*, so is a *bad* one!! Ceylon teaplanters should bear this in mind.

Rubber, they say, is to be planted up largely by some of the knowing ones. There certainly seems to be unlimited accommodation for this product. The Ceara variety gave us rather a scare in its wintering " vagaries," the leaves appearing as if stricken by some fell disease—rusty, speckled sunburnt, and finally drooping and drooping off. Fortunes they prognosticate are to be made of this adjunct to our planting enterprize *Nous verrons.* AU REVOIR.

AN ASSAM TEA PLANTER ON TEA IN CEYLON.

From Mr. Aitken's paper which we publish on page 980, it will be seen that this gentleman, who, equally with Mr. Cameron, has had experience in Assam and subsequently in Ceylon, though he does not feel that he can endorse the prediction of a yield of 700 lb. of tea per acre for Ceylon lowcountry estates, is yet quite certain, from what has been obtained from Calsay at 5,200 feet (some of the tea, we suspect runs up to 5,500) that Ceylon tea planters may calculate on an average of 5 maunds (400 lb.) per acre against 3 maunds (240 lb.) in Assam and Sylhet. We have a forcing tropical climate, fairly fertile soil, and regular rainfall; our labour supply is good and plentiful; we are exceptionally favoured in regard to means of transport and the sanitary conditions in our island are immensely superior, an important consideration in regard to native labour and the well-being of its European directors. The result of all these advantages is that, in Mr. Aitken's opinion we can produce tea at 32½ cents per lb. against 42½ cents in India. Mr. Aitken talks of this as a difference of 20 per cent in our favour, but it is in reality nearer 25 per cent, and the larger our yield per acre, of course the larger is the difference in our favour. This is surely encouraging, although Mr. Aitken may be right in saying that tea can never hold so important a position or yield such profits as the coffee enterprize did in its palmy days. Mr. Aitken is as much enamoured as Mr. Cameron was of the Maskeliya flats, Bitterne, Kintyre, Laxapana, &c., but his reference to Calsay and Rookwood, and his expressed opinion in favour of the superior quality and the profitable quantity of high grown tea, shew that the owners of places at high altitudes need not envy their brethren in the lowcountry. Yield may not be so copious in the alpine regions, but the climate is preferable and the soil is better, and with due precautions against wash, will probably be more lasting. For both low and high estates the prospects are exceedingly good.

But people must not kill the goose that lays the golden eggs; and we are sorry and shocked to learn from Mr. Aitken's paper, that in the greed for quick returns, tea plants are cut and hacked down at eighteen months old. All the literature of the subject led us to believe in only light plucking until the third year, that is according to Indian mode of counting, the third year from the nursery, which agrees with Mr. Aitken's second year from the planting. Full plucking should only commence with what would be the fourth year in the one case and the third in the other. What Mr. Aitken says about planting at stake agrees with the best Indian opinions; but our own experience leads us to repeat our recommendation of damp ravines as sites for tea nurseries. Moisture in such places reaches the seeds by capillary attraction and no shade is necessary. Then again our experience is that the strong tap-root of the tea plant, enables the product to flourish where the subsoil is stiff clay—subsoil into which the tap-root of the cinchona cannot penetrate. As regards distances apart, we see no reason to regret our adoption of 3×3 feet; and on steep inclines we only regret we did not put the plants at half this distance in the rows across the faces of the steeps. Mr. Kerkhoven, the leading tea-planter in Java perhaps, was in favour of " the hedge system" even at 1,500 feet elevation on gently undulating ground: 4 feet between the rows for cultivation, and the plants in the rows only 1 foot apart. This, of course, was for China plant, which we see Mr. Aitken denounces. We think he is right in giving the preference to good jat (variety) of hybrid. The hybrids originated in the introduction to Assam of China teas by Mr. Fortune, under the orders of Lord William Bentinck's government. The fact of there being an indigenous tea in the jungles of Assam was, curiously enough, held to indicate, not that this indigenous plant should be cultivated, but that the soil and climate would suit what were deemed the superior China teas! That was half-a-century ago, and Col. Money expressed regret, in which many will not share, that the China plant ever came to Assam to contaminate the indigenous. But a good hybrid, with large golden-green leaves is scarcely inferior to the indigenous in any quality, and is superior in robustness. Even up to 6,000 feet, our hybrids from the old Assam Company's estate flourish, but our small trials with indigenous have been disappointing. We are bound to state, however, that a jat strongly China, which Mr. Graham, a Darjiling planter, sold us as good Assam hybrid, and which at one time we were advised to root out, is now giving excellent returns, the surface of some of the bushes being remarkable. Our experience agrees with Mr. Aitken's in favour of well-grown nursery plants, small ones being naturally checked in growth. But there are great differences in the progress of tea plants according to season. When the first planters went to Assam about forty years ago, they found there the three varieties of tea: the Assam indigenous; the intro-

duced China; and the resulting hybrid. The pioneer work was done by Government who gladly retired in favour of that private enterprize which, in the face of vast difficulties, has done so much for India. Virtually commencing thirty years later, the prospect is that we, in Ceylon, shall more than compete with our Indian precursors in the enterprize, and, if the Indian estates have been all formed with locally grown seed, we cannot see any reason why that example as well as others should not be followed in our island. Granted, plants from good Assam seed, the seed of such plants ought to be as good as any imported.

GENTLEMEN,—I have been asked by your Honorary Secretary to make a few remarks on TEA, and its probable future in the upcountry districts of Ceylon, and I propose now confining myself to the following heads, namely, Seed, Land, Planting, Pruning, Picking and Yield.

Some 35 or 40 years ago, the pioneer planters entered Assam, which was at that time in rather an uncivilized tate, bringing with them tea seed from China, and also Chinamen to guide them in the cultivation and manufacture of tea. A considerable area was planted up in different parts of the valley, before it was discovered that a plant closely resembling the China bush, although larger in leaf and growth, was growing wild in the forests. Seed from this tree was procured and planted beside the China cultivation, and, in the fertilizing of the two jats, *i.e.*, the China and the indigenous, we have the hybrid, which is considered the hardiest and strongest yielder of all tea plants. There are of course many degrees of hybrid, but the kind preferred is the large-leaved, bright-green plant, leaning more to the indigenous, yet combining the hardiness of the China with the yield and strength of the former. I have been asked whether it would not be better to import seed from India in preference to the seed procurable here, and in reply I would say, *take* the best Ceylon seed if you can get it. No doubt there is better seed in India, but the difficulty is to get it here. The Singloo estate for example in Assam sells its indigenous seed at R120 per maund, and this, if procured, would doubtless prove a good investment, but, generally speaking, the risk is very great, both as regards soundness and jat. A really good hybrid sells for about R50 a maund in Assam; so it seems doubtful that you could buy the same article here in Colombo for R40 or R45. I must say, however, that I saw seedlings a few days ago in Mr. Skrine's nursery in Dikoya, raised from some "Amluckie" seed bought in Colombo, which were all that could be desired as regards jat. To those who contemplate large extensions, and who must import seeds, I would say buy from some reliable agent in Calcutta *yourself*, have it carefully packed, forwarded as soon as possible, taken *immediate* delivery of in Colombo, brought to the estate, sweated and planted, by which means it is quite probable that 75 per cent of the seed will be found good and germinate. I have heard that the China plant has been advised for the higher elevations of Ceylon. The idea is an utter fallacy. There is little or no excuse for planting China in Northern Assam, and there is less here, as our climate is a tropical one.

LAND.—The lays of land *best* suited to tea are the flat and undulating. There are some estates in Maskeliya, which I have seen, that answer to this description. By way of example I would mention Bittern, Kintyre and Laxapane; in Upper Maskeliya Alton and Glenugie are also suitable. The soils peculiar to the upcountry are, I believe, very favourable for tea, being light and friable, with a free subsoil, impregnated more or less with ferruginous matter, while the regular rainfall and tropical climate are conducive to a quick growth and regular flushes. I consider the labor in Ceylon as second to none in the east, and a point of the greatest consideration to the tea planter because it is owing to the facilities there are in procuring coolies, and working them cheaply that he will be able to produce his teas at a cheaper rate than they can in India. Assam at the present moment is very badly off for labor, and you can imagine the difficulty, when R80 to R100 for coolies per head is paid to contractors before they can be landed on the estate. For this sum you have an agreement for 3 years, much of which time the coolie may be down with fever, to say nothing of the loss incurred through mortality, which is heavy. Another advantage I would point out is that of cheap transport. There are few colonies better if so well off in this respect. Thus with a good supply of labor and cheap transport the Ceylon tea planter has the advantage of his brother in India, in that he can produce his teas at a lower figure, while the yield of tea obtained on an average is, we now know, much better.

PLANTING.—In planting up old coffee with tea, I would advise the holes to be cut about 15 inches deep, and about 8 inches in diameter. These again should be 3 feet × 3 feet apart on the steeper lands, and 4 feet × 4 feet on the flat. Sould the land be very steep I would advise it being planted up *closer*. As regards planting seed at stake and transplants from nurseries, I advocate the latter as being the safer method. Seed put out at stake in old coffee land have not the advantage of the original surface soil, while it runs the risk of being washed out by heavy rains, or being eaten off by poochies before it can get a fair start. Planting at stake is I know considered the cheaper way of putting out tea, but when you calculate the loss through seed not germinating, insect pests, &c., I think you will find the system of nurseries and transplants the cheaper in the end. There are supposed to be 32,000 seeds in a maund, and supposing it were purchased locally, and delivered the same week it was picked, I see no reason why 25,000 seeds *at least* should not germinate, and turn out well. When planting at stake in Assam 2 seeds at least (and often 3) are put into each hole, thus at 3ft. × 3ft., 4,840 holes to the acre, would require 1 maund of seed to 3 acres. Supposing again 25,000 seeds out of 1 maund of 32,000 germinate, and turn out well in the nurseries, they would be sufficient to plant up 5 acres at the same distance apart. The advantage thus clearly lies with the nurseries. It is a popular idea in Ceylon that all seed that floats in water is bad. This is not so. The slightest contraction of the kernel may make the seed float, while it may be quite good if sweated. I would not care to sell seed on these conditions. The best and fairest test I know of is that of taking 100 seeds or less, breaking them, and so finding out the percentage of good or bad.

NURSERIES.—In making nurseries, the land should be chosen in some level protected part or parts of the estate, where the soil is really good. Nurseries made on the side of a hill exposed, dry, and weather-beaten are seldom great successes, or so good as they should be. The beds again should be as broad as possible, say from 4 ft. to 5 ft., and the seeds put in 3 inches apart in regular lines, so as to enable the plants to come up evenly. As regards shade and protection, I am in favor of *sticking* in ferns, if procurable. They save wash and help to keep the beds damp, which is all that is required. Straw or grass is often spread on the beds, but it should be removed as soon as the seedlings appear, as its weight might hamper their growth if put on thick. I have noticed often that, in planting out here, very small seedlings not more than 4 inches high have been taken from the nursery. This is a great mistake. I would put out nothing, if possible, under 10 inches in height. I have always found that the larger and stronger the transplant the quicker start and growth, as there is no doubt that the smaller ones feel the cold and exposure, which, to say the least of it, must check their growth for a time.

PRUNING AND PLUCKING.—After a lapse of two years or nearly so, pruning and plucking will become the next considerations. These are most important stages, and are either the making or marring of the plant—at least for a time. Tea should not be pruned with a view to plucking before two years or more. I know that it has become the fashion in Ceylon to cut down 18 month old plants, and to bolster them up with cowdung, with a view to getting a crop. But I put it to you, gentlemen, as practical planters, whether the few miserable pounds of tea obtained can compensate for the stunted growth that must ensue. In Assam, where the growth is as strong, if not stronger than Ceylon, no young tea is touched with the knife before the end of the second year, and after that, it has a few months' grace before hard plucking is resorted to in its third year. It surely requires no tea expert to tell you that the tea plant requires *some* root, growth and strength before it can be called on to give a return, and I

have no hesitation in saying that, if this indiscriminate hacking and plucking of young cultivation be continued, the system will be found disastrous, and the result a temporary collapse of the plant. At the end of the second year, I would advise the young plants being cut across at from 2 feet to 2 feet 6 inches according to the jat. They will require little more, excepting that all low laterals touching or trailing on the ground be removed close to the stem. The subsequent prunings I shall not deal with separately. Sufficeo it to say that the ends in view are uniform height—good plucking surface, and the preservation of all strong woo capable of giving leaf. *Stick pruning*, the severest of all, is only resorted to, when the plant is exhausted from bad treatment or other causes, in which case it is cut down within a foot of the ground, and not tampered with again before it has completely recovered its original size. When the new growth or flush appears, it should be allowed to grow until it is 8 or 9 inches long, after which it may be tipped—no more. Tipping means plucking the top leaf *only*. The subsequent flushes are plucked to 2½ leaves, not counting the *pekoe tip*, and, as a rule, the trees should flush in from ten to twelve days according to the weather. I have heard that the pluckers go round in the lowcountry once a week, but I fear that is the exception. If they do, they must be plucking remarkably fine, or in other words taking off a growth that is scarcely a flush at all A very young flush of course makes fine tea, which may be a credit to the tea-maker, but I doubt if it remnuerates the proprietor, who must lose considerably by this system of plucking. A planter last week described the state of some trees he saw in the lowcountry, as a mass of stunted foliage. He referred to the effect of the plucking, and I believe he was not far wrong. A severe pruning in itself will do the tea bush no harm, but hard plucking on the top of it, *i. e.*, plucking again before the new shoots have matured is a serious mistake—in fact a blunder. I am told that proprietors, must have money, but what proprietor would sanction this treatment if he knew it to be prejudical to his plants? I think people are tired of strange theories and rash experiments, and I would advise those who are interested to thoroughly satisfy themselves before adopting any new system. All I can say more on this point is that the Calsay estate (5,200 ft.), consisting of about 40 acres of 5-year old tea, gave 2,829 lb. of made tea last month, and it has not been *cut down* or overplucked. I do not propose going into the details of manufacture, which I daresay are familiar to you all, beyond comparing the high and lowcountry qualities of tea. As yet I think the "Rookwood" Estate, at a high elevation, has the advantage in average prices, but I am not certain as to the yield per acre of that estate. There is little doubt that the estates from 2,500 feet elevation downwards will give a larger yield per acre than the higher districts, but I doubt if there be a *very* great difference, as we have much better soil as a rule, although we may not have the forcing climate.

My experience of the quality of the high and low grown teas is that the latter has more strength and pungency, while the former *almost* makes up for this in the flavor peculiar to all hill *growths*. I do not think therefore that there is any advantage to speak of on either side in this respect. In putting his crop into the market, the tea maker does not look so much to *one high-priced* tea, as to a good general average, and if R40 per maund *nett* be averaged, a fair profit should be shewn. Say that we have 200 acres in its sixth year, giving 5 maunds per acre. This makes a crop of 1,000 maunds which at R40=R40,000. Against this we have an expenditure of R130 per acre amounting to R26,000, which leaves a profit of R14,000 on the working of the 200 acres. After a careful estimate of the expenditure on an estate giving 5 maunds per acre, I consider that R130 per acre is no under estimate, provided the necessary machinery is supplied. Should there be a greater yield than 5 maunds per acre, the profit would of course be greater, with little extra expenditure, according to the amount of leaf the machinery is capable of working up to *yield*. The average yield of tea per acre in India is a little over 3 maunds per acre, if that; while the average cost of production is as near as possible, 42 cents per lb. delivered in Calcutta. There are many estates which yield much more, but, taking all the old China cultivation into account, I think the above figure about correct. In Ceylon up to the present time we have every reason to believe that our yield per acre will far exceed this, and I do not think I am above the mark when I say that 5 maunds per acre may be confidently expected on an average upcountry estate. I have estimated the expenditure with machinery at R130 per acre, which with a crop of 5 maunds brings the cost per lb. to 32½ cents delivered in Colombo.

It would be absurd for any stranger like myself to come forward and predict with any degree of certainty, an excessive yield, such as 7 or 8 maunds per acre, in this district without first having some basis upon which to argue. I have said 5 maunds or 400 lb. per acre, because Calsay:—a place known to you all—gives me strong hopes of yielding that crop next season.

Thus the difference in cost of production between Ceylon and India is 10 cts. or say about 20 per cent in favor of Ceylon.

In conclusion, I would again lay before you the main points of vantage in comparing our prospects with those of India. First, we have good labour and plenty of it, cheap transport, regular rainfall and a good yield of leaf per acre, all of which are essential to the success of the industry. Assam, on the other hand, can boast of few of these advantages, while her labour question is as likely as not to bring her into further difficulties. I am positive that, given a crop of 5 maunds to the acre, we can put our teas in Colombo for 32½ cents per lb. and perhaps less, while I am as certain that the Assam, Cachar and Sylhet teas delivered in Calcutta, cost at least 10 cents more. This difference in cost of production is, of course, our strongest point. We can make as good teas, and for less money, and, whatever may be the result of the depression now in India, our future, as far as tea is concerned, is, I am convinced, a bright one. Although tea can never altogether take the place of coffee, and give the same large profits, yet it is sure, and, as a staple product will help to bring back the prosperous times of which we stand so much in need.

W. H. AITKEN.

Harrington, Dimbula, 3rd May, 1883.

TEA BOXES.

The late action at home reported in the *Home and Colonial Mail*. regarding injury to tea in transit brought out a point of great interest to all concerned in the industry, and one which to some extent no doubt accounts for "soft," to which we have been endeavouring to draw our planter friends' attention lately. Within the last five years since wood became dearer, and greater precautions were taken by Government to prevent the reserves being intended on, tea boxes have deteriorated much in the qualities of the wood they are manufactured from; and the greatest caution is now necessary in dealing with the box contractors. Say ten years ago the fact of cotton trees being used for tea boxes was unheard of, but now-a-days it is by no means uncommon; and judging from the stench this wood has when raised out of the water to be madeinto boxes, we do not wonder at tea deteriorating even with a sheet of lead between it and such a stench. Mangoe wood is now-a-days becoming more common. We wonder if any of those new woods have been subjected to chemical analysis, or whether their suitability for the purpose to which they are put, has been practically tested before being filled with tea, made into boxes, and shipped off to London to take their chance. The woods most commonly in use for boxes are mangoe (*aum*), Koorba, Sotrong, Toola (or cotton) Jalna and Teak. The last mentioned is not in use in Cachar, but is much used by the large companies in Assam Proper. We ourselves give no opinion regarding those woods beyond what is well-known to every planter. The cotton tree is extremely soft and porous, and if not well seasoned, after manufacture is very full of water, andy very liable to dry-rot, &c. From this we should say that the *toola* or cotton wood is to be

avoided, and should never be used, if possible. Mangoe or *aum* has a strong resinous smell, and should, we think, be used with caution until the fact has been well established by carefully conducted experiments, whether it really injures the tea or not. It is only within the last few years that it has been introduced to any extent, and we must not forget that it was during the same period that the deteoriation in the staying powers of our tea has been complained of. It would be worth the while of some of our planters to keep a chest for a year or so, and report the result. Koorba and Sotrong have been in use many years, and we have never heard any complaints beyond the fact that they were not so durable as some of the hard r woods; and that more breakages were reported on arrival in Calcutta than amongst the others. Jalna and teak are both hard woods, but the great drawback to their use is their very heavy weight which makes them undesirable, especially in the case of gardens which have much land carriage. Toon or cooma wood is, we believe, used in Darjeeling. This should be a good tough wood as well as being light, and could be made up into very neat looking packages. Mr. Sibthorpe when down in Australia, and when in America, several times noted that there was great room for improvement in the matter of boxes; and his comparison with the China boxes was anything but favourable. In Calcutta for furniture the cooma or toon wood is in much request, and we see no reason, if this is a suitable wood for tea-boxes, why for a very small extra outlay a really respectable box could not be turned out. Let our planters once take the thing in hand, it will be done. At the present moment there is probably no more clumsy, unwieldy looking thing than an Assam tea chest; and the rough exterior is, we doubt not, much against its taking in a new market. A very small progressive move in this respect has been made by one firm in Calcutta in decorated tea-boxes; but the price is prohibitive to any large consumption. We fail to see why our brethren in Assam should not be equal to the occasion and get up nice packages, trim and neat, and fit to put along-side of the Chinese. We feel sure that the indomitable British spirit of enterprise has only to be properly aroused to get it done. If ¼ inch thick wood is enough to keep together China tea, why is it not enough for Indian? These are points which every planter should think over and endeavour to improve, as every little, helps in the struggle now going on for existence.

[To the above article from the *Indigo Planters' Gazette* we would add our already often repeated hope that erelong paper may supersede wood as material for tea boxes. Subjected to the tremendous pressure which proper machinery can effect, paper ought to have all the solidity of wood of the same thickness, say ¼ inch, and ought to be equally capable of being dove-tailed and bored for nails. The material could be sent out in shooks of pieces ready prepared or in sheets to be cut to different sizes. Ultimately the cost of carriage might be saved by the manufacture of papier-mâché, properly varnished in India and why not in Ceylon? Has any experiment in this direction been made?—ED.]

THE CINCHONA ENTERPRIZE: SUPPLY AND DEMAND.

We quote from the *Madras Times* a letter from a South-East Wynaad planter who re-sings a song which has already been repeatedly chanted, the burden of which is that cinchona culture in the east and west is being overdone, and that the supply will erelong exceed the demand. There is, no doubt, much truth in the warning notes, and the wretchedly unremunerative rates at which twig bark has recently sold add force to the arguments used. In talking of the hundreds of thousands of trees planted in India, Ceylon, Java, Jamaica and other places, we must not forget our experience here in Ceylon of the enormous proportion which "dies off" or "cankers" before coming to maturity. There is also no doubt that, in the case of quinine and the other fever-curing alkaloids, there is, beyond most articles of human use, scope for extended consumption. The only limit, indeed, is that of cost, and what has happened and is happening in the case of coffee and tea will certainly happen in regard to cinchona bark: low prices will encourage consumption and demand will continue even in the face of higher prices. There is wisdom in the advice given to cultivate only the best kinds, but with this qualification, that robust trees, such as succirubra, the renewed bark of which seems to improve with every shaving, may prove to be ultimately the best.

COCHINEAL.—Cochineal is the body of the female cochineal insect dried. This insect exists on a species of cactus, and when alive is about the size of a ladybird, or perhaps a trifle smaller. It is wingless, rather long, equally broad all over, and is marked behind with deep incisions and wrinkles. It has six feet, which curiously enough are only of use directly after birth, and it secures itself to the plant by means of a trunk which is found between the fore feet, and derives its nourishment from the sap. The male cochineal is like the female only during the larva period. It changes into chrysalis, and eventually appears as red flies. The female deposits some thousands of eggs which she protects under her body until they are hatched, and on the appearance of the young ones the parent dies. While the young are in the larva state their sex cannot be determined. They lose their skins several times, and while the female fixes herself on the plant, the male, after getting over the pupa state, is winged. Two or three months is the extent of the life of these little insects. They are gathered before they lay eggs, and are then rich in colouring matter. About 70,000 insects are said to go to the pound of cochineal.—*Export Prices Current & Trade Report.*

PIONEERING WITH NEW PRODUCTS.—A capitalist interested in Ceylon writes:—"Many people now disbelieve in rubber cultivation ever being made a paying investment in Ceylon. Had Ceylon been blessed with Governors of sense we would years ago have had demonstrated to us, in different localities in the island, which new products could be made to pay. No man cares to become a pioneer in new products, be he ever so wealthy. When the Government authority, the Director of Ceylon Botanical Gardens, gave it as his opinion that the days of coffee were numbered, it must have been the manifest duty of Government to set about to demonstrate the capabilities of the island for new *products* at various elevations. Had this been done, the exports today of these new products would almost have equalled in value those of old King Coffee in his prime. As in the case of Samson, now that the main pillars have gone, *all* (even Government officials) with all the coffee (Samson) perish (or nearly so) in the one catastrophe. But this talk of "perishing" is nonsense: coffee is not yet dead, old Sol is in an erratic mood and playing truant with good seasons. Coffee will yet pay magnificently."—Our correspondent must remember that Governor Gregory most energetically and personally interested himself in "New Products." In his time, "cinchona," "tea," "cocoa," "rubber," were honoured with special headings and paragraphs in the annual Address, and, in order to give reliable information for the benefit of absentees who pay great attention to what a Governor says, Sir William visited every district where experiments were carried on. It was part of his policy, too, to establish Experimental Gardens for new and old products in every province in the island.

TEA IN AMBAGAMUWA, CEYLON.

Imbulpitiya tea has topped the London market in the sales reported by last mail, thus maintaining the high reputation of Ambagamuwa for tea. Although less than three years old this tea plantation has already given crop at the rate of 400 lb. per acre, while we are credibly informed that Galbodde tea in full bearing will have yielded for the year ending 30th June next at the rate of 800 lb. per acre !—about 700 lb. having been gathered up to date.

GRAPES GROWN IN COLOMBO.

We have received the following :—

Colombo, May 14th, 1883.

The Editors, "Ceylon Observer,"

"MY DEAR SIRS,—I send you per bearer a small parcel of grapes from a vine growing in Hillebrandt garden at Wolfendahl, and shallbe glad to have your opinion on the same. There were about 500 bunches but I am sorry to say nearly four-fifths were destroyed by the rain and black ants. Is there any remedy for the latter?—Yours truly, C. H. DE SOYSA."

The bunches of grapes sent to us are simply magnificent: the fruit being large, fully formed and of fine flavour: Mr. de Soyza ought to have had his tree with 500 bunches photographed from different points of view, and as to the ants the vine well deserves to be thoroughly protected with a glass house, tar and other means being used to prevent the ants getting in. We have to thank Mr. de Soysa for this very acceptable gift,

RESUME OF VARIOUS METHODS FOR DETERMINING THE TOTAL ALKALOIDS IN CINCHONA BARKS.

H. Meyer, of the Pharmaceutical Laboratory at Groningen has carefully examined and compared the various methods in vogue for determining the total alkaloids in cinchona barks, and has further worked out a new method of his own. In the *Archiva der Pharmacie*, November 27, 1882, he gives the following *résumé* of his investigations :—

1. When finely-powdered cinchona bark is boiled for an hour with freshly-prepared milk of lime and 90 per cent. alcohol, the whole of the alkaloids present in the bark is brought into solution.

2. Previous maceration with dilute sulphuric acid or alcohol acidulated with this acid is only useful in cases of imperfect extraction, as in the method of Prollius (see the Chemist and Druggist, 1881, page 397), and does not yield better results than the extraction with milk of lime.

3. In the separation of the alkaloids themselves, repeated extraction by agitation with the solvent is far preferable to precipitation.

4. The separation of chinovic acid, chinovine, and a certain wax-like fat may be effected without loss by mixing the alcoholic infusion, previous to evaporation, with an excess of sulphuric acid, and then evaporating gradually under constant stirring. The above substances are then found in a state of fine suspension in the liquid, and admit of being completely washed out.

5. Only by means of protracted decoction and displacement of the cinchona lime is it possible to extract the entire amount of alkaloids present in the bark operated on.

6. According to H. Meyer's modified lime-alcohol method the total percentage of alkaloids in a given bark may be ascertained in twelve hours, or with ease in two days.

7. All other methods of extracting the cinchona powder, either by means of dilute adids (de Vrij, Hager), mixtures of chloroform and glacial acetic acid (Eykman), or chloroform, alcohol, and ammonia (Prollius) are imperfect, a considerable quantity of alkaloids always remaining in the bark.

8. The methods of Professor Gunning and Prollius give too high results, for impurities, such as calcium chinovate, chinovine lime, and a wax-like fat, are thereby reckoned among the alkaloids, and calculated as such.

The following table will afford a view of the results obtained by the various methods. The figures represent in part the average of a number of analyses.

Method	Percentage of Pure Alkaloids		
	Cort. Cin. Succi., Javaneus	Cort. Cin. Calisayæ.	Cort. Cin. Offi. (P.G.)

—*Chemist and Druggist.*

PLANTING IN BUNDABERG, QUEENSLAND.

The recent resistance offered by the working class of whites to the introduction of Sinhalese to one of the sugar districts of Queensland, and the consequent failure of this effort to increase the labour supply there, has brought into some notice the district of Bundaberg, where the disturbance occurred. By the kindness of a former resident there, now in this Colony, we have read a pamphlet by Mr. Andrew M. Goodwin, a reprint of a series of articles in the "Bundaberg Mail," giving an account of the sugar industry in the district, up to December last, and as it may interest our readers to know the position in which settlers there are now placed, we give an abstract of the information it contains.

Bundaberg is a thriving town on the river Burnett, ten miles from its mouth, 70 miles north of Maryborough, and 272 miles north of Brisbane. Between the river and the Pacific Ocean is a volcanic formation called the Woongara Scrub, twelve miles long by eight wide, the soil of which is said to be of the first excellence in the growth of sugar. In 1879 there were two factories on the banks of the river, near the town. Now besides older mills on the north bank, there are eight crushing mills of varying capacities, from 550 to 2,000 galls *per diem*, sending their juice to a large refining factory, and six complete sugar plants, capable of turning out from 2½ to 8 or 10 tons sugar *per diem*, besides others in course of manufacture and some estates depending on their neighbours for getting their cane crushed. Most of these are in the Woongara Scrub, * one or two only being on the northern bank of the river.

The Woongara Scrub is a rolling piece of country forming a sort of flattened ridge, between the sea and the river of no great height, but rising sufficiently towards the centre to form a mound so distinctive as to be of use as a beacon to guide vessels in making the mouth of the river. This elevation, known as "The Hummock," is reserved from clearing operations in consequence of its service in this way. The Woongara Scrub is a dense jungle of vines and trees,

* "Scrub" in Australian parlance signifying forest.—ED.

far larger, says our informant, than any in Fiji. He describes its soil as red and sticky, very absorbent of moisture. and of great fertility. Throughout its extent there is a large quantity of volcanic scoriæ and tufae and the soil of Loma Loma is almost identical. There are some clearings on it here and there, but the larger portion is still in the natural scrub. The cane grown there is described as of "surpassing growth and full of saccharine richness." As it approaches the sea and river on either side it becomes open timber land, and the soil assumes the character of a rich black loam. This has been used for some years as a grazing country, but it is now intended that the greater portion of this also shall be planted with sugar-cane, for the cultivation of which it is said to be equally well suited with the scrub lands. The returns are said to be equal to three tons per acre. This portion also includes the point where the river debouches into the Pacific, and the whole extent of it has lately been purchased by a syndicate, for the purpose of breaking up into suitably sized farms, to encourage settlers, of small or large capital. This has been done, and the lands were advertized to be sold by auction last month, in sections of various sizes, from 20 to 400 acres. A new town is projected at the mouth of the river, the sections of which are also offered for sale. At the point where the proposed town is to be built, the river is six fathoms deep thirty yards off the bank and wide enough to allow large steamers to turn while steaming. It is therefore claimed to be a most favourable position for steamers calling. From this train lines are projected all through the estate, and it is anticipated that a railway, connecting with Maryborough, will shortly be carried out.

At the end of 1882 there were 4,300 acres under cane, out of a possibility of 50,000 acres, more or less, about 3,000 acres of which had been crushed or was fit for crushing. The richness of the juice had been spoiled by frost, and it only showed a density of 6° to 8,° though one or two patches are reported at 10°. This danger of frost is one to which the lands on the inland side, or with a westerly aspect, and on the banks of the river are liable, though it appears to be of rare occurrence. On the sea ward side the cane was in no way injured, even by the severe and unusual frost experienced last year. The labour employed has been European and Polynesian, but this is the hill of difficulty there as here. Indeed, our informant tells us they are far worse off there than we are in Fiji, and it is mainly on that account he left the district. We observe in the account before us that one planter endeavoured to work his mill entirely with white labour. "In this laudable attempt, however, he failed, for on the first Monday morning after commencing operations only *one* man put in an appearance, the others being either discontented with the 'hardness' and 'muckiness' of the labour or dissatisfied with the wages they had agreed to see the season through for." No wonder this planter declares that, "if he had to depend on European labour to attend his sugar mill, he would not grow a stick of cane." The numbers of Polynesians seems very insufficient, for, though they are not given in all cases, there does not seem more than an average of twenty-five to each plantation, including mills and all. These are to some extent supplemented by "free," what we call "time-expired," Polynesians, but withal it is evident this is the main drag on the advance of this district in sugar cultivation. It is said "unless the labour difficulty is made easier of solution than it is at present, speculative operations will cease, for none of the planters feel justified in risking capital on the very doubtful chance of securing the necessary labour to enable them to obtain any return for their expenditure." "Even at the present juncture there are insufficient labourers to attend to the different places, and to extend operations is simply out of the question."

On the whole this seems to be a splendid sugar district could it be utilized properly, and it does seems very suicidal on the part of whites to try to exclude labourers, who must certainly increase the wealth of the country and the necessity for exteuded white labour at the same time. As things stand however, labour is king, and capital and splendid land must lie idle until it can be moved. Private accounts state the Indian labourers brought were far from being what was wanted. They were not farm laborers, but billiard markers, professed thieves, jail birds, and vegabouds of every description. The planters there are now turning their eyes to China, where, they are informed, they can obtain an unlimited supply of real farm labourers, who will cost landed, including the £10 poll-tax, not more than £18 or £20 : five years' men at £22 per annum including everything.—*Fiji Times.*

[Frost is a serious objection, but want of cheap labour is still more serious. We see the Mackay planters were about to indent on New Guinea for labour, but the more feasible plan will be for sugar planters to go where there is good soil, plenty of labour (if the natives of New Guinea will work for planters) and no frost.—ED.]

SORGHUM AS A SUGAR-YIELDER.

The impression we have received from all we have read of experiments with sorghum as a substitute for sugarcane in America is that although sorghum, especially the amber variety, has merits of its own, it is not likely to supersede sugar-cane as a source of fine well-crystallized sugar. The Indian papers contain a report of an experiment made in the North-West Provinces, which seems to promise profitable results because the richly glucose, honey-like *gur* (something like our jaggery produce) suits the taste of the people, who are large consumers of sugar. One of the chief articles of food in the North-West of India, indeed, is a cake made of wheat flour and sugar, while sugar confections of all kinds are also much used. The sorghum, being a gigantic millet, has the additional advantages of yielding grain before the canes are cut, while the leaves and stalks are greedily devoured by cattle. The hope expressed is that sorghum may yield a sugar for local consumption, so setting free that derived from the sugar-cane for export. But India seems capable of absorbing any possible quantity of sugar that can be made, the very tobacco smoked by the people being largely mixed with the produce of the sweet cane, while a favourite drink is sugarcane sherbet The thirsty pilgrims at Benares go to a boutique, put down a small coin, are supplied with a bit of sugarcane, a pair of squeezers and a cup, and they go their way refreshed. It seems that the juice of the sorghum is specially acid, requiring treatment with lime and soda, and it is amusing and somewhat disgusting that castor oil is used to help forward the process of crystallization. If there were a market in Ceylon for sorghum sugar, the plant could, no doubt, be cultivated wherever maize or "Indian corn" will flourish. From the paper referred to we make a few extracts :—

The experiments were directed solely to procuring the best possible sample of crystalised sugar in the compost form (gur). So far as could be understood from the re-

ports receive from other parts of India, no saleable gur had yet been made, and even in America the manufacture of anything but syrup would seem to date from about 1861. Experiments were tried with various re-agents for defecating and clarifying the juice which is intensely acid, much more so than that of sugarcane. Canes were cut at various stages of growth to ascertain the most profitable period. Canes were ground with the leaves on to economise the labour for stripping. The worm-eaten canes were excluded. So a great deal of the crop was used to gain experience and scarcely as much was used in the manufacture of the best samples as would warrant the building up thereon of a commercial scheme. For this another season or two must be awaited. The best results were arrived at by stripping the canes in the field, carrying them straight to the mill as cut, putting them through a Bihia mill at once, and boiling the juice in one pan, as soon as removed from the mill. The best time for cutting the canes is when the seed is in the dough stage. The head of seed is cut off with the top short, and left in the sun to ripen, the whole of the seed being saved. As economy is a great point, a portable mill that can be carried to the field is a desideratum. Fermentation converts crystalisable sugar into uncrystalisable. So does the acid in the juice at high temperatures. Fermentation is set up in the juice on exposure to the air; hence the necessities for getting the canes pressed and the juice neutralized as quickly as possible after cutting. To prevent fermentation also the mill, boiling pan, and vessel for holding the juice as it comes from the mill were daily fumigated with a few sulphur matches. A few drops of castor oil were sprinkled on the juice as it approached boiling point to aid in clarification, and at boiling point, milk of lime was added carefully to a point close on neutrality. The scum as it rose was carefully removed and the juice concentrated down to the proper consistency for gur. A small quantity of "rab" was made from which drained crystals were obtained as a sample: but attention was chiefly concentrated on making gur. The above details show no difference from those of the process of manufacturing gur from sugarcane, as now practised by many manufacturers. It is only given in detail because although gur may be made from sugarcane juice, without using lime, a skilful native sugar-boiler entirely failed in operating on sorghum juice without lime, and for the black sorghum the failure was maintained even with lime, until a small quantity of carbonate of soda, or sajji, had been aided as well as the lime.

The analysis by Messrs. Carew and Company, Limited, of a sample was as under:—

Cane sugar	61·00
Glucose	23·85
Moisture	7·99
Ash	3·15
Unknown	4·01
Total...	100·00

This analysis shows for refining purposes an objectionable amount of glucose and a larger amount than was present in a sample of sorghum gur manufactured this year, also, at the Aska Sugar Works in Madras. The sugar would clearly be more suitable for brewing purposes than for refining purposes so far as export is concerned. But a peculiarity of glucose sugar is, I believe, its similarity in taste to honey, a taste which was very marked in some samples of the sorghum gur and which seems to be to the liking of the people. Coming as it does out of season and forming a good eating gur, there is testimony from both Carew and Company and from Messrs. Thomson and Mylne that it will fetch a top price in the market. It may possibly then become at least as popular for eating as sugarcane gur, and so free a large quantity of the latter for export particularly, if as may be hoped, further experience will lead of further improvement. Sorghum requires no irrigation, nor does it require much manuring. It can be grown on high light land which grows ordinary kharif crops, and has in America been cultivated year after year on the some soil without deterioration. The seed is all saved and is good food for man or cattle, while the tops, leaves, and begass are all eaten greedily by cattle. It is worth then the closer attention of Indian agriculturists; and a large supply for distribution should be intended of the best Early Amber variety from America against the coming kharif season.

CINCHONA CULTIVATION: ITS FINANCIAL ASPECTS.

A planter, S. E. Wynaad, writes:—There has, within the last 3 years, been quite a rage for cinchona planting. Everyone has taken to planting cinchonas, to a great or less extent; and we all have, or have had hopes of making fortunes out of the bark, and being able notwithstanding the fickleness of our old love of coffee, to retire some of us after many years of exile, to England, and those home comforts which memory paints for us in the brightest hues.

The cinchona-mania has some *raison d'etre*. Money has undoubtedly been made, and is now being made, from cinchonas; and estimates, drawn up by authorities on the subject shew us what handsome profits are still likely in their opinion to be derived from the cultivation. But, looking at the rapid extension which has been made in cinchona cultivation of late, the question naturally arises will the demand for, and consumption of, the bark keep up with the supply, so as to insure paying prices some years hence, when trees now being planted will have reached the producing stage? Philanthropists may rejoice when "the bitter blessing" is brought within reach of the poorest in the land; it will be well for the world generally; but will it be altogether satisfactory for the individual planter? Though he has his fair share of the milk (unadulterated) of human kindness; it was not philanthropy alone which induced the planter to spend his best years in fostering the Fever-slayer; *cela va sans dire*. Neither was it revenge on the malignant goddess Malaria, for a shattered constitution.

I calculate that there are now growing in Pykara, Neddiwattum, Ouchterlony Valley, and S. E. Wynaad, 5,000,000 cinchona plants; 10,000,000 may be put down for North and South Wynaad, Ootacamund, Coonoor, Kotageri, Kartary, Koondahs, &c., giving a total of 15,000,000 plants for the Wynaad and Nilgiris. We have besides Mysore, Coorg, Travancore, and other districts in Southern India, and Sikhim and Darjeeling in the North, where cinchonas have been extensively planted; and I do not think I would be far wrong in putting down another 15,000,000 as the number of plants now growing in these parts; giving, with the cultivation in Wynaad and Nilgiris, a total of 30,000,000 plants for the whole of British India. During the next two planting seasons, 1883 and 1884, I believe a larger number of cinchonas will be planted out than in any previous years; and by the year 1890, there will be in British India not less than 40,000,000 cinchona trees (yellow, crown, and red barks) none of them less than 5 years' old, with an annual producing power, allowing ¼lb. ℔ tree, of 10,000,000lb. of bark, that is to say more than half the amount of the present average annual outturn of bark in South America from all sources. Then there are Ceylon, Java, Jamaica, Mexico, and other countries which have gone, and are still going, in largely for this cultivation; and though it has been reported that the South American cinchona forests, owing to the wholesale harvesting, are rapidly decreasing, it is difficult to get reliable information on the subject, and it seems unlikely that South America will cease to be a large producer of bark for several years to come. I do not think it would be too much to put down the production of bark, in 1890, in countries other than British India, at 40,000,000lb., which would bring the whole world's production to the grand total of 50,000,000lb., annually; or, as far as I have means of learning, more than double the present annual consumption, and, even, allowing for a large yearly increase in the demand for bark, far more than is likely to be required to supply the world's wants at that date.

At the present time, inferior bark (twig and branch) is not worth shipping; being "a drug" in the market the druggists will have none of it; and if the German brewers want to make use of it instead of hops for their beer, one would naturally suppose that they would be willing to give for it what would at least pay the grower for the freight and charges, especially this year when the supply of hops was reported to be short. It remains to be seen whether the price of a great deal of our stem bark will not, within the next few years, fall to a point at which it will barely pay us to grow it. There is scope for the extension of the consumption of quinine of course,

but it is not unlimited scope. Those countries favoured with cheap labour, and suitable soil and climate, may be able to derive fair profits from cinchonas for some years to come: and amongst cinchona growers, he who is most careful in the selection of his seed and gets a strong-growing variety with rich bark to flourish on his land, will be better off than others. But to those who may contemplate going in for cinchona cultivation, I would point out that the grand results talked of as having been obtained and being now obtained by some in this branch of agriculture, may, as far as they are concerned, be relegated to the limbo of past possibilities.

I am not myself a scientific man, but there is what may be called the scientific side of Cinchona cultivation which cannot be ignored in looking at its financial aspect. As a cinchona-grower, I have to call in the aid of the scientist to make *analyses* of different barks for me in my selection of the best parents from which to get my plants in the future. It might be well for a cinchona planter to be able to make his own *analyses*; but, after all, the number of *analyses* he will require, for all practical purposes, will be few. Unless he may hope by judicious hybridization to get a variety richer or stronger growing than any that has yet been found, and thus make a name for himself (for the desire for fame may be found even in the jungle-wallah) his expenses in the way of getting necessary *analyses* made for him will not amount to much. A planter can, or ought to be able to, tell from the growth of a tree (be it of the yellow, brown, or red bark family) and the *appearance* of the bark, whether it deserves his special attention. There is, as everybody knows, in the cinchona tribe, a great range of richness in quinine—from the *Grey-barks*, with hardly any quinine in them at all, to some of the *Ledgerianas* which have given over 13 per cent of this precious alkaloid. Some of the best *Ledger* plants are of shrubby growth, and though they may give, when mature, over 10 per cent. of quinine, it is a question whether it will not pay the planter better to go in for a stronger-growing tree with only half this percentage of quinine in the bark. It will, however, be the endeavour of every cultivator in the future to grow as rich a variety as he can get to take kindly to his soil and climate: and it follows that, by this selection ("natural selection" of the fittest!) of the best varieties of cinchona, and, for the purposes of propagation, the best parents amongst these varieties, steadily continued in future years, the average percentage of quinine in the bark reaching the different markets must go on increasing annually.

Putting down the quantity of bark produced, we get in 1883, 25,000,000 lbs; in 1890, 50,000,000 lbs; and in the year 1900, 1,000,000,000 lbs. But whereas the average richness in *quinine* of total bark gathered in 1883 is 1½ per cent: the average in 1890 will be 3 per cent. and in 1900, possibly 4½ per cent. So that, though the *quantity of bark* in the years 1890 and 1900, will be respectively twice and four times that of 1883, the *quantity of quinine* will be respectively four times and twelve times greater.

To state the case in another form: in this year (1883), barks giving under 1 per cent of quinine are all but unsaleable; in 1890, barks giving under 2 per cent. and in the year 1900, barks giving under 3 per cent of quinine will be in the same unfortunate position.

The curative properties of quinidine and cinchonidine (and in a lesser degree cinchonine) are now being thoroughly recognized; this ought to raise a little the value of red, relatively to other barks which are richer in quinine, if it has not done so; but, for the purposes of my argument, it was unnecessary to notice any but the principal alkaloid. My figures do not pretend to be more than a very rough approximation; in a statement of this sort, this could not have been otherwise. We cannot predict with certainty what may happen by the year 1900; Wynaad may then have lapsed into jungle, and Mr. Gupta be Viceroy of India! But if it can be shewn by any of your planting readers that my figures are far wrong, or that my statement of the position of cinchona cultivation is founded on a misapprehension of the probabilities, nobody will be more glad than I.

I have written simply and purely for the sake of ventilating a view with regard to the future of chinconas, which, as one directly interested in their cultivation, is acusing me (possibly others also) considerable uncasiness.—*Madras Times.*

PEPPER CULTIVATION ON THE WEST COAST OF INDIA.

[BEYPORE, 20th April.—Referring to your enquiry *re* pepper cultivation sent to our Coimbatore friends, we have obtained the information we think you require, shewing how pepper is cultivated on this coast, and enclose same. —STANES & Co.]

THE PEPPER SHOULD BE PLANTED IN LOW, FIRM GROUND. In the beginning of the month of June, when the rain falls incessantly, at the foot of a jack, mango, cajou, marcim, or any other trees whose bark is rough or prickly dig a hole one foot deep, the breadth and length six inches. Into this hole put a cutting from the extremity of one of the branches of a pepper vine, then fill it up with earth, taking care no water is therein, and that none may remain after planting. In the month of July roots will extend themselves in the ground and the sprouts will appear on the surface, when they are to be tied to a tree, and a circular bank of earth thrown up round them that they may enjoy the moisture of the water, which remains on the ground and sheltered from the heat that prevails from the month of July to October. When the rains cease, cover the root of the vines with fresh leaves, it matters not from what tree, so that they have the quality of cooling. If the ground is too dry, water the same morning and evening; but, if it is entirely cool, twice in eight days is sufficient. Then plant five or six sprigs at the foot of the same tree, taking particular care that they in no wise touch each other. Ten days after the rains set in, remove the leaves that cover the root of the vine, pull up the grass that may have grown near them, and demolish the circular bank of earth made to contain the water, that none may remain at the foot of the tree. In the month of August repeat the same. The vines are to be cherished in this manner for three years. It must be observed that the foot of the vines should be covered every year in the manner beforementioned. If the vine is once smothered by the heat, it will begin to languish and produce no fruit; so it is necessary to follow the above instructions. The leaves ought likewise to be removed in the month of June, to prevent the white ants from reaching the root of the vine.

THE MANNER OF PLANTING IN THE MONTH OF FEBRUARY, WHEN THE GROUND IS LOW AND FIRM.

Having made hole ten inches from the tree, the depth thereof being fifteen inches, the length and breadth twelve inches each, take seven branches from the extremity of the vine, cut them thirty inches long, and put them into the hole; then fill it three quarters with earth, and the remainder with fresh leaves, observing to put water thereon, morning and evening, till the commencement of the rains, when fill the hole with earth, and throw up the bank as before directed. The time for planting these vines, in the rainy season, is in the month of June; and in the month of February in the dry season. If they are planted at any other time, they will not bear fruit. Trees planted for the support of pepper vines ought to be fifteen or sixteen feet as under. If closer, the branches will shade the vines from the sun, and they ought to receive a moderate amount of warmth.

MANNER OF PLANTING IN THE HIGHER SITUATIONS AND FIRM GROUND.

Make a square whole fifteen inches, the same distance from the tree, take ten branches from the extremity of the vine of seven inches length each, put them into the hole of a certain distance, filling it with earth and treating them as before directed. Two years after they are planted it is necessary to throw up a square bank of earth round every five plants that the rainwater may soak in and nourish the roots. If this is omitted during the rains, the vine will not subsist during the dry season, on account of the heat. This square is to be repaired every three years by which means the vine will live a long time and produce plenty of pepper; it ought to be done during the rains, in the month of July.

MANNER OF PLANTING IN VERY HIGH GROUND.

Make a square hole 2½ feet deep, at the same distance from the tree, take 12 slips from the extremity of one of the vines, two feet nine inches long, put them into a hole at a certain distance, and cover them as before directed throwing up the square bank. It is necessary to plant these vines at the time before-mentioned. The reason for making the whole deeper is on account of the heat which

prevails on high places. Vines planted in a strong soil will not produce any fruit, because the roots cannot extend themselves with facility.

A sandy soil is equally prejudicial to them because it is naturally hot; and the heat of the sun penetrates with more facility than in any other ground.

You may plant vines in a place where fresh water communicates itself in the same manner as in ground entirely low and firm; but I doubt very much if they will produce pepper. If they yield any I am certain the grapes will be of no great account, because of the continual moisture the plant will receive. I have already remarked it is absolutely necessary that the vines enjoy an equal degree of heat and moisture, if you think of gathering a good crop.

MANNER OF PLANTING THE PEPPER GRAIN.

Take ripe pepper and put into water for three days, at the end of which take off the skin, and, after you have mixed good red earth, with cow dung and water, put the pepper into it, exposing the same to the sun for three days, early in the morning and evening; it is necessary this mixture be neither too thick nor too thin. After this plant the same in an earthen pot, every grain at a certain distance, taking care to water them every day with a waterpot, until the stalk has four leaves. Then dig a hole at the foot of a tree, two feet deep and nine inches long and broad, take cow dung and ashes of all sorts of firewood, put it into the hole, and mix the same with the ground dug out of it, taking care to fill it in such a manner that there only remains five inches of elevation. Fifteen days after, plant four pepper vines in every hole, cover them with earth two inches deep; during the summer water them every day, morning and evening, and cover during the rains. Likewise take care that no water remains at their feet, by covering them with earth. As soon as the rains are over, throw up a circular bank of earth round them to contain the water they are watered with. In this manner they must be nourished for three years; in the fourth year they will begin to give fruit. These instructions are to be followed every year. These proper plants are planted either in high or low ground, but it is necessary it be very firm.

MANNER OF PLANTING WHERE SALT WATER IS.

After having made a hole, thirteen inches square, at the foot of a tree, fill the same half up with good red earth without mixing it in the least with salt water; then plant therein ten slips of those vine, at a certain distance, and cover the same with good red earth. When the rains are over, throw again red earth at their feet, and make a circular bank round them, to form a conservatory, for watering them every other day, taking particular care to cover the feet of the branches with fresh leaves. In the beginning of the rains, fill the conservatory and take away the leaves, observing to pull up the grass that sprouts at their feet, covering them with red earth, at the same time spreading same round about. They are to be nourished every year, as is pointed out at the beginning of these instructions.—*Indian Agriculturist*, September 1878.

COFFEE TRADE OF SANTOS.

BY CONSUL WRIGHT.

The production of coffee was already fast outstripping consumption when, early in 1880, the Brazilian Government saw fit to become an exporter of the article, with the view of placing funds abroad to meet its obligations instead of as hitherto making remittances in bills of exchange; thus entering the Rio market as a buyer in competition with legitimate exporters, and upsetting for the time being all calculations as to exchange, not only preventing the then natural decline of prices out here, but really causing an advance to a point relatively above the simultaneous market value abroad, and depressing all foreign markets by throwing their shipments almost *in toto* upon one, New York, especially at that time, when a combination was endeavouring to "corner" coffee, thereby causing greater caution on the part of the general trade and anxiety in Europe that New York might be compelled to ship part of her stocks thither.

The operation of the government resulted in a loss stated to amount to at least 800,000 milreis, to say nothing of its consequences upon legitimate mercantile trade. As a matter of course, I would not allude thus to the transaction had it not been so freely discussed in and out of Parliament and in commercial circles everywhere for some time past as to place it beyond the pale of official reserve.

Looking at the then tremulous state of the coffee trade (so often before afflicted by speculative rings which resulted disastrously), owing to the visible and increasing overproduction everywhere as compared with consumption, it is considered to have been unwise on the part of the Government to have struck the first blow at the downward tendency because if left to merchants regularly and legitimately in the trade, they would have known how to have met the anticipated natural changes. But even this was denied them by the public assertion of the successor to the minister of finance who executed the commercial measure alluded to, that he approved of the course of his predecessor, and would repeat the operation if he saw fit, while the operation has lately been defended in the Imperial House of Representatives, although ably contested. All this causes nervousness in the trade now, as for some time past, lest such an operation might suddenly be predicated.

There are those who believe that the Brazilian Government is interested in the great Havre ring, but I am not one of them, however plausible their deductions drawn from the past year may appear. It may be that the operation I have alluded to may have given birth to the hope of these wealthy French speculators that it might be repeated either wholly or on account with them, but they have apparently been left to carry their own burden. They may have been and may still be influenced by the hope that the reported negotiation between Brazil and France may result in a commercial treaty, resulting in a diminution of the exorbitant French duty on coffee amounting to more than the invoice cost, with freight and marine insurance added, so as to offset some recompense on this side for the importation of real French wines, instead of the Hamburg concoctions imported and sold as French.

In my No. 66, dated January 16, I spoke of the Havre ring, with its enormous coffee stock hanging as an incubus over the the trade, and so it has continued. In September its Havre stocks were represented to have cost £3,000,000 sterling, against the market estimated value £2,000,000 sterling, or a straight loss of £1,000,000 sterling, not including expenses of "carrying," previous losses, &c. Several large failures also have occurred there; yet a reinforced concern seems to have been organized, and is apparently determined to continue the same course. Why Santos and Santos coffee should have been alone selected for these speculative operations is puzzling, but so it is. Certain is it also that the Brazilian coffee trade has changed, assumed a new form; for whereas formerly the large importers sent out orders and letters of credit for purchases, of large parcels and cargoes for sale there to jobbers; now-a-days these very jobbers have become importers, and to such an extent that the old importers are almost driven from the field. Nearly all the firms in Santos and Rio have head or branch houses, or partners, or agents abroad, through whom they offer to sell for immediate or future shipment a given quantity of coffee, quality as per type sample there shown, at a fixed price in foreign money, this price including invoice cost on board and freight. This enables the jobbers and retailers to buy out here instead of there, where they were so often in the meshes of speculative cliques. Now they know that on a certain day they will have their supply and its cost, they running no risk except the loss of the vessel, and hence their expected supply, all other risks falling upon the vendor here. They obtain letters of credit just as others do, and settle for the drafts drawn in virtue thereof payable at ninety days after sight in London, Paris, Frankfort, etc., just as readily as if they made the purchase in warehouse at New York, Havre, Antwerp, Hamburg, etc., on sixty days' credit, to be paid for in cash as "taken from store, with discount." But the system is a bad one and may yet result seriously, and this seems to be the opinion of many who shun such, on a principle well founded. The risks run by the party out here are many and serious: among them, quality sold not obtainable, prices advanced, exchange rates advanced, absence of steamers and vessels, rainy weather preventing shipments within specified time, fires, etc. If all these are to be feared in contracting for shipping "short," how much more for "long" delivery?

I am informed that coffee has been sold to Havre, quality and price agreed upon, for shipment here "along up the end of March, 1883. Coffee is therefore sold which may not exist, as myriads of pods or dried berries are still on the bushes, and may or may not inclose beans or burnt, oilless kernels. Then, again, this is a rainy climate

and the main stem of our railroad system may again be damaged on the Serra and traffic interrupted, as we have often seen before, thus stopping supplies, which would of course interfere with the fulfilment of these future delivery contracts. Nothing can show more plainly how the trade has been cut up than Table V., in my dispatch No. 84, made up from the invoice book of this consulate containing the number of invoices certified to. The number for 1882 would have been greater had not a large buyer in New York, for its roasting purposes, opened branch houses at Rio and here and ship their coffees in large invoices. The small invoices, then, point to the fact that the consignees are many, and perhaps a number of them are in our interior cities and towns.

Laying aside the Havre operations, the same is the case with Europe, where it seems many cities and town have their respective little combinations for importation and division among individual members thereof. A house here not long ago shipped per steamer to Hamburg 2,000 bags, divided or cut up into fifteen invoices for delivery all over Germany at different points. I was told that the largest invoice was for 1,000 bags. This house is one of the oldest, wealthiest and most reliable import and export firms here, able to do what they wish, but nothing with type samples futures or speculation as now conducted. You will thus see that the Brazilian coffee trade has been brought down nearly to a Ceylon writer's notion of "plantation to cup."

The prices of coffee here are very low as compared with former years, and much is being said and written about it both here and abroad, and the Government and Associations are engaged in promoting the display of samples in Europe and the United States, with the view of bringing Brazilian, especially Santos coffee better before consumers. If an exportation of 1,500,000 bags cannot show what Santos coffee really is I fail to see how a few finger-picked samples, showing what it can and ought to be, but representing what cannot be had, can have any good effect. Far better would it be to have an exhibition of samples of coffee from other producing countries at some central point in the province where the planters might go and see that planters in those countries send to consuming markets for sale the same coffee that their own cooks, after picking and washing out stones, chaff, &c., roast and prepare for the table. No one can or will deny that the flavour of Santos coffee is not equal to any other, but it hurts the planter to see it quoted so much below others abroad, and to be told that it is mixed with and sold as some other kind at the quoted market price for such kind. Nothing more reasonable than this, for if the planter deems it more to his interest to send down for sale his crop containing one-fourth stones, dirt, unsightly, valueless, black, and ashy beans and husk, he ought to expect it to be sold at a price here which will allow some margin for cleaning it abroad and putting it into the same condition for roasting and raising as he himself uses.

Too many coffee trees have been planted, and hence the fruit is not properly harvested and prepared for market, and planters are reported as confessing this. Well-prepared coffees are sent down and fetch relatively high prices, both here and abroad, but being exceptions, are not generally quoted. And if the actual low prices here leave a loss to the planter, which, however, I do not believe he must blame himself in tacitly protecting the high and exorbitant railroad freight charges. These railroads pay dividends at the rate of ten to fourteen per centum per annum. All but one are native enterprises, in many instances, many planters being large shareholders, who grumble at low coffee prices, but not at their railroad dividends. The railroad freight and charges average 5 milreis on every bag of coffee sent to Santos; the average sale price today is about 17 milreis per bag (60 kilogs. or 132 lb), not including very ordinary and triage, of which there is a large quantity in store not worth on an average over 9 or 10 milreis per bag, which, deducting all other charges will leave little or nothing for the planter. The planter must now clean his crop very much better so as to send down a better quality, send down a smaller quantity and obtain comparatively higher prices, paying or rather not paying, freight on unsent trash, and cause railroads to be satisfied with less incomes and smaller dividends; otherwise Mexico may teach them a severe lesson.—*American Mail.*

TO MAKE TOUGH MEAT TENDER (see p. 967).—Please try Fig leaves for softening meat, as I recommended in your Journal years ago. You might do well to wait until you have some grown in the open air, as those grown under glass might be less efficient than I found them in Algiers. The common Nettle is considered in Belgium to possess the opposite properties, and is much used for wrapping up such delicate things as trout, crayfish, game and other delicacies, when sending them out in baskets.—JEAN VAN VOLXEM.—*Gardeners' Chronicle.*

MANGROVE FRUIT.—Misprints are a source of trouble to all editors and words similar in orthography are often confounded. The most recent case occurs in the *Queenslander* where "mangoes" has been changed by *composite diablerie* into "mangroves," thus:—"Orchards of a tropical character are not at all unfrequent in the coast lands near Brisbane, and conspicuous among them is Green Hill nursery and orchard, owned by Mr. A. Williams at the eight-mile Plains. His mangroves this year have produced particularly good fruit, the flavour of most of them being excellent, especially the 'rose' and the 'strawberry' varieties, and others with which we have had the pleasure of tasting. To give our readers an idea of them it is only necessary to state that some of the larger ones were nearly 1½lb. weight."

PLANTING TEA WITH COFFEE.—With reference to "Vera"'s rather despondent letter and estimates on page 991, we may briefly say that while he puts R60 per acre as the cost of planting up coffee with tea and cultivating &c., several planters think it can be done, with care and economy, for not more than R40 per acre. One point cannot be pressed too strongly on planters of tea, and that is to have their supply of plants well matured before going to the expense of clearing new land or of holing coffee-land. One authority goes so far as to say that plants might well be left more than a year in the nursery with advantage, and we learn of a case where 150,000 *two year* old nursery plants put out last season have done so well that this year they are being cropped, thus saving cost of a year's weeding as well as interest on planting on new land, and saving the coffee one year longer on old plantations. First, then, let the would-be tea planter make sure of his nursery and of a good supply of fully-matured healthy tea plants.

EUCALYPTUS LEAF OINTMENT.—Josephson's Ointment is of Australian origin, being the property of Messrs. E. Row and Co., of New South Wales. In the colonies it has achieved, we believe, considerable success in the treatment of wounds, etc. It is, we are told, prepared from wild plants that are peculiar to Australia, these plants being "met with nowhere except on that continent." What these plants are we are not informed, but their efficacy on being transformed into an ointment is testified to by a number of testimonials published by the English agent, Mr. Dawson, of Macclesfield. As some of these date back as far as 1874, the ointment can scarcely be considered in its infancy. It is in composition a vegetable extract, and quite harmless, and is very cooling in its action. For sores of all kinds, and for burns, chilblains, piles, etc., it is especially recommended. Since writing the above our attention has been drawn to the following paragraph in explanation of the composition of the ointment:—"Of the various families of plants peculiar to Australia, none is of greater importance, both from a scientific and an industrial point of view, than those comprised in the class of *Eucalypti* or gum trees. There are in all over one hundred distinct species in this family, some, of the larger varieties being giant forest trees, attaining a height of upwards of 200 feet. Besides timber of a superior quality, they yield gum, tannin, and other products of economic utility. It is to the medicinal virtues of the *Eucalypti*, however, that particular attention is directed. The leaves of several of the species, when duly prepared and compounded into an ointment, are found to possess healing properties, which, without exaggeration, may be termed remarkable."—*Export Prices Current & Trade Report.*

Correspondence.

To the Editor of the "Ceylon Observer."

THE BABOOL (*ACACIA ARABICA*) TREE.

London, 20th April 1883.

SIR,—In my No. 5 "New Commercial Plants." I pointed out the probable value that the babool tree (*Acacia Arabica*) would obtain.

I am glad to be able now to inform your readers that the dried pods have been tested here, and they are found to yield about 60 per cent of tannin matter: this is after the seeds have beeen extracted. There is no value in the seed; therefore it would be better to let the pods dry on the place where they are cultivated, and then extract the seed, and press the pods and send them home.

The action of this tannin produces a beautiful light-coloured leather, and I feel sure that it will be worth while growing this tree. It is a native of India and the West Indies; so there will be no difficulty in obtaining stock direct.

Valonia is now worth £18 a ton; so this ought certainly to be worth £40, but owing to the tanners being so peculiar and really not knowing when they get a valuable and rich tannin substance, they often allow such drugs as Balsamocarpum, which yields four times as much as Valonia, to lie in the market unsold at £18 to £20 a ton; whereas, if they knew the value of it, it would be worth to them £40 to £50 a ton for the *pod*.

Owing to the diffusion of information by Mr. W. N. Evans, the greatest authority on practical tanning, many of the tanners are having the water they use analyzed, and where it is hard they are precipitating the lime and in consequence obtaining very beneficial results.

I can only give you from time to time the matters that pass before me in this country, and I do hope that some of your scientific readers will give the public the benefit of their experience of the Babool tree, and if it is easily cultivated when it fruits, &c.

I do so miss the *Tropical Agriculturist*, my copy having gone astray.—I am, sir, yours obediently,

THOMAS CHRISTY.

TEA IN FIJI.

Alpha Estate, Tavinni, Fiji.

DEAR SIR,—I should esteem it a favour if you would be kind enough to insert Mr. Moody's letter and the report in your valuable journal. I have the pleasure to draw your attention to a number of the *Federal Australian*, particularly No. 88, of November last, in which an article on the capabilities of Fiji appeared, and on which a leader was written. If you consider these worthy of notice in your columns, I am sure much interest would be felt by many of your readers.—Believe me, faithfully yours,

JAMES E. MASON.

Hon. James E. Mason, Tavinni, Fiji.

Melbourne, 16th December 1882.

Dear Sir,—I duly received yours of the 31st October and also samples of teas which have been carefully examined, and further I sent them up to the laboratory for analysis.

The result I duly sent to the *Argus*, *Age* and *Telegraph* newspapers, and it appears in the two latter papers copies of which I send you, and I also enclose clipping from the *Age*. The *Argus* so far has not published it.

To the report I have little to add. The teas are excellently fermented, but the firing should have been brisker, but beware of burning or smoking. If you can turn out tea like the samples, you are sure to sell such teas freely and at good paying prices. Any way it proves fine teas can be grown in Fiji. The analysis is very satisfactory. Only Ceylon teas have gone so low in mineral ash as yours. The highest extract obtained from any tea never went beyond 53 for Ceylon, and the average of Foochow teas rarely exceeds 34: so yours at 45·21 and 45·80 are very high. The soluble salts, in comparison with the mineral ash, are very high. The percentage of theine 1·73 and 1·86, is also good. Some China teas lately arrived only went ·43 to ·90.

The appearance of both teas with their rich tips is very good, though for keeping I prefer the grey black to the black colour of your teas.

It is very difficult to value a new article, but my values are near enough, and would probably be realized for small quantities of like samples to those you forwarded.

The notices I sent to the press, because it is a new thing in this part of the world, and also it will help it on in selling the tea next year.—Yours very truly,

J. O. MOODY.

P. S.—18th.—The *Argus* puts it in today's issue.—J. O. M.

(*Extract from the Melbourne "Argus," November 18th*, 1882).

TEA FROM FIJI.

The Hon. James E. Mason, of the Alpha tea and coffee estate, Tavinni Fiji, has forwarded to Mr. J. O. Moody, tea expert of Melbourne, samples of the first Fijian tea produced, accompanying it with a letter stating that early next year he hoped to pluck off 30 acres planted with tea, and that the samples sent were hastily prepared in a barrel with a fryingpan of charcoal. Mr. J. O. Moody's report on the samples is as follows:—

"Fiji Pekoe.—Leaf, handsome, small, even, golden-tipped pekoe, evenly and well fermented. Liquor, very strong, full, rich and pungent pekoe flavour, thick with deep red infusion: an invaluable tea for mixing, and worth about 2s 6d per lb. in bond.

"Fiji Pekoe Souchong.—Leaf, well-made, wiry, twisted, rich black tippy leaf, evenly and well fermented. Liquor, strong full, rich, and ripe, true pekoe souchong flavour, with good bright-red infusion: a fine tea to drink alone, and worth about 1s 9d per lb. in bond. These teas have the character of good Ceylon growths, and are in every respect suitable teas for general consumption. Such samples are sure to meet with ready sale in Australasia or Great Britain."

Mr. Frederic Dunn, Analyst, Industrial and Technological Museum Laboratory, under date the 12th November 1882, reports on the same samples:—

"Upon analysis they give:—

	Percentage of Moisture.	Percentage of Mineral Ash.	Percentage of Extract (Total).	Percentage of Soluble Salts.	Percentage of Theine.
Pekoe ...	9·00	4·36	45·80	2·98	1·73
Peke Sonchong	8·85	4·40	48·28	3·00	1·86

"The percentage of mineral ash and soluble salts found in these teas closely resemble the amount obtained from the Ceylon exhibition teas. Taking into consideration that the above samples are the result of an experimental trial, the results are highly satisfactory, and the analysis speak well for Fijian teas."

True copy.—James E. Mason, Tavinni.

TEA DRYING BY STEAM.

2nd May 1883.

DEAR SIR,—Referring to a communication in your paper of the 21st ult., under the above heading, I may explain that its publication was premature. It contained only a crude idea, and the details given are meant rather to illustrate the principle than to describe what I consider the completed machine.

The drawings and descriptive letter were submitted by "Teksab" to an expert of his acquaintance for an opinion on the same with a request to return them, which was overlooked.

The main feature in the machine is the arrangement for producing any desired temperature above 212° by generating steam under a corresponding pressure. That this can be effected with perfect nicety by a pressure valve was shown in the letter referred to, and my object in writing now is to point out that the danger of explosion will be very much less than you might

conclude from the remarks of the expert to whom you submitted the matter.

I annex a series of temperatures with the relative pressures. From it you will see that the pressure corresponding to a temperature of 280° (beyond which no tea machine should be worked) is only 36 pounds, not 75 as your referee implied. The machine will be made of steel plates, and, as they will nowhere be more than 1½" to 2" apart, they may be strengthened to any required degree by ribs of ⊢ iron. The distance at which these ribs should be placed and thickness of plates required in order to bear with *perfect safety* a maximum pressure of 36 pounds are mere matters of detail.

By the way, I can't help questioning your expert's competency to give a verdict in the decisive terms he uses, or he must have glanced at the thing in a very cursory manner not to have seen that, in this case, flat surfaces could be strengthened to bear almost any pressure and this without seriously encroaching on his "small fortune." May I ask further for particulars of a few of the fatal explosions caused by the "sudden contraction" of steam in India? That steam-driers have been tried in India and abandoned is no reason why they should not be tried in Ceylon, as I may remind you that in more than one instance Indian failures have been carried to a successful issue in Ceylon.

I may add that, instead of having steam led into the apparatus from a detached boiler, as suggested in "Teksab"'s letter, the machine will be its own boiler, and, in working, would be filled with water to above the level of the top tray, so that it will be not steam but water at a temperature of 280° which will be in contact with the drying plates.—Yours faithfully,

JOHN R. K. LAW.

P.S.—I have seen Mr. Shand's letter, pronouncing the idea an infringement of his patent. Are we to conclude that this patent covers all possible and impossible applications of steam—that in short he is the inventor of steam? As well might Mr. Laurie claim that all the recent transplanters are infringements of his original patent, since, like his, they are all made of tin. J. R. K. L.

TRANSPLANTERS AND TRANSPLANTING.

2nd May 1883.

DEAR SIR,—In reply to "Planter"'s enquiry in yesterday's issue, I have seen Davidson's envelopes with Scowen's transplanter, worked alongside of Wilton's, Moir's, Wright's, F. Laurie's, and two others; and they (Davidson's envelopes and Scowen's transplanters) in every case superseded the others. In addition to the very low price (partly as they are not patented, and partly as they are so simple) they are much quicker, less liable to get out of order, and simpler to work than any other that I have seen. A transmuter and 100 tins can be got for about eleven pipees.—Yours faithfully, TRANSPLANTER.

AN ABORTIVE LIBERIAN COFFEE TREE.

Badulla, May 8th, 1883.

SIR,—I am forwarding to you by this post a small parcel containing two samples of Liberian coffee cherries, 3 of each, marked No. 1 and No. 2.

You will find No. 1 contains no matured beans, nothing but leafy matter, while No. 2 is as it should be.

The No. 1 cherries are taken from a tree 6½ years ago, planted at an elevation of 3,000 ft. on Serendib estate in this district and well sheltered. It is in fair average soil among Coffea Arabica but has a clear space all round it of from 12 to 15 ft. It has blossomed for the last four years, but till now has never set its blossoms and not a single cherry has been picked off it. This year, to all appearances it is bearing very well, but up to date not one matured bean has been found in 100 cherries picked. The husk is to all appearance *cankered*. A small black mark shows on it after it has swollen to a decent size, which gradually developes and dries up the husk.

The tree is an isolated one, no other Liberian coffee tree being near. It is topped at 5 feet and receives attention in the way of handling and manuring and forking, having had cattle manure forked in round it once a year for the last three years. It has been very free from leaf-diseass for the last 15 months, and I have never seen leaf-disease on it beyond the pin-spot stage during the last four years. At the present time there is not the slightest sign of disease.

The No. 2 cherries come from the trees at the other end of the estates, about half-a-mile distant from No. 1. The trees are 3½ years old and have cropped well since the second year. There are several of them close together, and none of them have behaved like No. 1.

Can it be owing to its isolated position and want of neighbours that this strange behaviour of No. 1 is due? It appears to me to be as great a puzzle as the "No. 1" of Irish notoriety! I am, yours faithfully,

P. FRANK HADOW.

YARROW LEDGERS.

Yarrow, 13th May 1883.

DEAR SIR,—With reference to the sale in Colombo of the small parcel of Yarrow ledger bark reported in your columns the other day, I would feel obliged if you would mention that the parcel contained a very small percentage of stem quill, being mainly composed of prunings. The trees, having never been pruned up since they were planted, had become in places so thick as to exclude the light, thereby both hindering the growth of the smaller trees and preventing the larger ones from blossoming freely. It was therefore necessary to remove some of the lower branches, and it was from these principally that the bark was obtained. A few trees were also cut out, but in all cases these were such as had yielded an inferior result on analysis (below 7 per cent) or small trees of inferior growth. None of the trees of high analysis were removed. I mention this, as the analysis of the bark, 5·77, may appear a poor one, taking into consideration the very high analyses of individual trees which we have received. W. F. L.

THE RUBBER TRADE OF THE UNITED STATES.

Colombo, 15th May 1883.

DEAR SIRS,—Why characterize the paragraph about "Indian Rubber" in the *American Mail and Export Journal* as an exaggeration? The figures given are strongly coroborative.

For instance, we have 30,000 tons, say 60,000,000 lb. of raw rubber imported, worth $60,000,000; plus 270,000 tons of cotton, shoddy, &c., also entering into the manufacture

certainly worth $16,000,000, total $76,000,000 for raw material, the value of which would surely be more than trebled in the manufacture. Thus $250,000,000, are obtained, which is more than equivalent to the £50,000,000 your contemporary of the "Times" lately quoted, and, unless you are prepared to show that the import of raw rubber into the United States was considerably less than 33,000 tons last year, you are wrong in calling the American editor's statement "an exaggeration!" Certainly, you cannot condemn figures given in a *Census Bulletin* for the year 1882 upon the strength of a newspaper's loose statement for the year 1880! And a striking feature which you would do well to call your readers' attention to is the increase in value of the raw product in six years from 48 cents to $1·25 cents per lb.—Yours truly, W. MOREY.

[The sooner Mr. Morey, as Consul, refers the question to headquarters the better, and he will probably find that a printer's error is accountable for the 250 millions dollars worth of rubber manufactures: the Census Bulletin may be all right and the *Mail* all wrong.—ED.]

MOSS GROWING ON COFFEE TREES AS COVERING FOR CINCHONAS.

DEAR SIR,—Has any one tried moss growing on the stems and primaries of old coffee as a covering for cinchona trees, as I have never seen it done, and would recommend some of your readers to try how to apply it best.

Sometimes grass for thatching the trees growing through coffee is not to be had within reach, and in such a case moss will be found a cheap covering for trees large enough to be worth the labour, while the coffee trees will benefit by its removal.

I have tried it on a small scale, and so far it appears to answer the purpose well.

The plan I have taken is, after removing strips of bark for quill off a tree, to lay on moss under old shingles and tie firmly with coir, beginning at the bottom of the stem and working upwards. Perhaps dead coffee leaves might be a substitute for moss, put on and secured under shingles; but this may draw attention to *material* at hand for experiment, and how to make it of use.—Yours truly, FOG.

PLANTING TEA AND CINCHONA ON MORTGAGED COFFEE ESTATES.

DEAR SIR,—At this time proprietors are planting up their coffee estates with tea. I would ask for whom, *i. e.*, for themselves or for their mortgagees? Let us take a not unusual case—a 200 acre estate that during the last 4 years has dwindled down from 5,000 to 1,000 bushels parchment and over which there is a mortgage of R50,000 at 8 per cent and from which say 5,000 rupees worth of cinchona shavings and toppings can be obtained annually at present. I am speaking of holing and planting plants, and propose the first year to plant 100 acres between the coffee rows only, at 3 feet apart; the second year to plant the other 100 acres the same way; the third to plant up the coffee rows in 100 acres 3 feet apart, taking out the coffee; the fourth year to plant the coffee row of the remaining 100 acres, taking out the coffee: so at the end of the fourth year you have 50 acres 4 year old, 50 acres 3 year old, 50 acres 2 year old, 50 acres 1 year old tea and no coffee. To keep the coffee and planted tea in order, to plant 50 acres tea yearly, to plant and harvest the cinchona, I do not think R60 per acre is a high expenditure. Taking the above figures and taking 4 years, what is the result?

	Profit.	Loss.
1st year expenditure 12,000		
Interest ... ... 4,000=16,000		
Value of cinchona ... 5,000		
Value of coffee ...10,000=15,000		1,000
2nd year's result is the same		10,00

3rd year you take out 100 acres of coffee, but may fairly increase the return from cinchona, say:—

Value of cinchona ... 7,500		
Value of coffee .. 5,000=12,500		
against interest and expenditure 16,000		3,500
4th year you have no coffee but say profit of 10 cents per lb. on 7,500 lb. tea, say	750	
and value of cinchona ... 7,500	8,250	
against expenditure and interest of...	=16,000	7,750
or a total loss on the 4 years' working of ...		R13,250
which added to the mortgage above-mentioned		50,000
makes a debt on the estate of		63,250
or say as the last year's expenditure was not reduced		60,000
and you may have:		
50 acres 4 year old tea worth R300 per acre ...		15,000
50 ,, 3 ,, ,, 250 ,, ...		12,500
50 ,, 2 ,, ,, 200 ,, ...		10,000
50 ,, 1 ,, ,, 150 ,, ...		7,500
and cinchonas worth perhaps		30,000
making the whole estate worth		75,000

and an estate which would not give you profit after paying interest for perhaps 2 years longer. Few mortgagees can wait so long for their money, and, if there are not buyers, there is small chance of borrowing R60,000 on an estate valued at R75,000: in fact a tea estate has been made for your mortgagee. There may be other better ways of planting tea through coffee, and planting at stake may be cheaper; but I think the yield of coffee will be lessened by tea growing thickly through it. I don't say I am correct, but I should like to see the subject discussed. My estimate is a very rough one and can very easily be picked to pieces. Cinchonas grow, and more bark can be harvested, but cinchonas also die; we may get better coffee crops, but we may get worse, and are specially likely to when tea is sapping the soil. Great reduction of interest by mortgagees aided by better coffee crops would help the proprietor more than anything. Let the visiting agents in their reports, instead of condemning coffee, tea and cinchona, condemn the high rates of interest, and they would do good to the proprietor, mortgagee and the country. —I am, yours faithfully, VERA.

CURIOSITY OF TREE GROWTH.—An interesting observation on tree rings is recorded by Prof. Bachelart in *La Nature*. During a visit to the ruins of Palenque, Mexico, in 1859, M. Charnay caused all the trees that hid the façade of one of the pyramids of the place to be cut down. On a second visit in 1880, he cut the trees that had grown since 1859, and he remarked that all of them had a number of concentric circles greatly superior to their age. The oldest could only have been 22 years of age, but on a section of one of them he counted 250 circles. A shrub, 18 months old at most, had 18 concentric circles. M. Charnay found the case repeated in every species, and in trees of all sizes. He concluded that in a hot or moist climate, where nature is never at rest, it may produce not one circle a year as with us, but one a month. The age of a monument has often been calculated from that of trees that have grown on its ruins. For Palenque, M. Larainzar calculated 1,700 years, having counted 1,700 rings in a tree. M. Charnay's observation requires the number to be cut down to 150 or 200 years, making a considerable difference, a matter of 1,500 years. Prof. Bachelart asks whether M. Charnay took account of certain coloured rings which some tropical trees present in cross section, and which are to be distinguished from the annual circles.—N. W. LUMBERMAN.—*Journal of Forestry.*

MATURITY OF WOOD.—The question is often put, At what age is wood of the different species of trees most profitable and advantagously cut as a ripe and mature crop? This is not a simple but compound question, and requires a somewhat lengthy explanatory answer. Two things in particular contribute materially in determining the age at which each species of tree should be cut as properly mature. First, the situation and kind of soil on which the tree grows; second, the number of trees upon the ground and manner in which they were thinned at the various stages of growth.—*Gardeners' Chronicle.*

CAMPHOR ASSISTING THE GERMINATION OF SEEDS.—It is, I believe, not generally known that most seeds are greatly hastened in their germinating process by being soaked, previous to sowing, in soft water, to a pint of which a lump of camphor about the size of a large nut has been added. I have tried this experiment on many vegetable seeds, such as Peas, Beans, &c,, as well as Palms, Ricinus and various other tropical seeds, which we often receive with very hard testas, many of which would require soaking for a long period in the ordinary way; but with the addition of camphor, as before stated, only a very short period of soaking is required. When time will permit I intend undertaking a series of experiments relative to the value of camphor, &c., in influencing or hastening the germination of seeds generally, and will, with the Editor's permission, communicate the results in these columns.—T. W. S. LEE.—*Journal of Horticulture.*

MALARIA IN ITALY.—An Embassy report from Italy in referring to the subject of malaria in the country, which is very great, says the chief causes of the complaint are attributed to stagnant water and the destruction of timber. It is poined out that while in France the forest service costs the State 14,000,000 francs per annum, Italy spends no more than 150,000 lire. France has laid out 23,000,000 francs on rewooding her forests during the past twenty years; Italy in five years has completely denuded of timber 1,500,000 hectares of land. Emigration increased from 19,000 persons in 1876 to over 40,000 in 1879, to a great extent on account of the malaria. The sole practical effort to combat this plague has been made by the individual energy of the French Trappists at the monastery of Tre Fontane, near Rome, where they have planted Eucalyptus trees on a large scale in one of the most unhealthy parts of the Campagna.—*Gardeners' Chronicle.*

"NATIVE BREAD."—A few specimens of a curious tuberous body, which occurs in small quantities in clayey soil in Jamaica, have been forwarded to us with the following account by Mr. J. Hart:—"It is apparently of fungous origin. It may be an edible species of Tuberacei. It is found about 2 inches from the surface of strong clayey pastures at 5,000 feet elevation; mean temperature 63° Fahr. The specimens are found solitary, at very irregular distances from each other, and of different sizes, at all seasons of the year. They are often discovered on the surface after heavy rains, the wash from which has carried away the surface soil." Mr. Hart's specimens at once reminded us of those which were sent more than twenty years ago from Travancore by Horaninow under the name of Mylitta lapidescens, Hor., and which are figured in *Linn. Transactions*, vol. xxiii., tab. 9, fig. 14—17, and they are doubtless identical, though coming from such a distant locality. They accord closely in structure with Mylitta australis, a fresh specimen of which was sent both to Tulasne and Corda, and figured by the latter in his *Icones*, vi., tab. ix., fig. 93, from which it is clear that the affinity is with Endogone, but unfortunately perfect fruit has never been seen. The production is well known in Australia under the name of "native bread," and there is no doubt that it is perfectly wholesome, but the Jamaica specimens are too small to make them of any economic importance. The white veins consist of threads less compacted than those of the intermediate mass, the tips of which swell, and doubtless are the infant state either of asci or spores. A long account of similar matters will be found in the *Journal* of the Linnean Society, vol. iii., No. 10. The Travancore specimens are used as medicine by the Chinese, but, like many other of their remedies, are of very doubtful utility, and perhaps rather dependent on their nutritious property, like Salep, than on any sanative attribute.—M. J. B.—*Gardeners' Chronicle.*

TEMPERATURE OF SOIL AND "CANKER" are thus noticed in the *Journal of Horticulture*:—Barren cankered trees have been cured of their disease, and their barrenness replaced by fertility, by simply having their roots lifted out of the cold under soil and placed near the warmer surface. Dr. Lindley, quoting from the Memoirs of the Caledonian Horticultural Society, in his "Theory of Horticulture," mentions a case of this kind. Mr. Reid of Balcarras cured cankered trees by taking their roots out of soil which at 3 feet deep was during the summer months 44°, at 18 inches 50°, at 9 inches 57°, and at 6 inches 61°. In a raised border where the soil was dark we, ten years ago, found a thermometer indicate 67° 6 inches from the surface; near by, on the level, it was only 59°. The border, it should he added, had a slope of 25° or thereby.

AN ANGRY TREE.—A very entertaining and amusing scrap-book could soon be made by any one who would take the trouble to cut out paragraphs on the idiosyncracies of plants, and the various other items of information on botanical and horticultural subjects, which appear in newspapers. Performances altogether putting into the shade anything recorded by the author of *Freaks and Marvels of Plant Life* are gravely related. The following, recently published under the above heading by more than one London daily, is a good instance in point:—"A singular species of Acacia is growing at Virginia, which shows all the characteristics of a Sensitive Plant. It is about 8 feet high, and growing rapidly. When the sun sets its leaves fold together, and the ends of the twigs coil up like a pig's-tail, and if the latter are handled there is evident uneasiness throughout the plant. Its highest state of agitation was reached when the tree was removed from the pot in which is was matured into a larger one. To use the gardener's expression, it went very mad. It had scarcely been placed in the new quarters before the leaves began to stand up in all directions like the hair on the tail of an angry cat, and soon the whole plant was in a quiver. At the same time it gave out a sickening and pungent odour, resembling that of a rattlesnake when teased. The smell so filled the house that it was necessary to open the doors and windows, and it was a full hour before the plant calmed down and folded its leaves in peace."—*Gardeners' Chronicle.*

CASTOR OIL PLANTS.—Few plants that are grown for the beauty of their foliage are more ornamental than the different varieties of ricinus or castor oil plants, which are not half so much grown as their merits deserve, as not only are they suitable for pots, to use for the embellishment of large conservatories or halls, but they are grand outdoors, where, if planted as single specimens on lawns, dotted here and there in borders, or grouped in masses, they produce a striking effect. If arranged in the last-named way, the stronger sorts should be placed in the centre, and the weaker around, that the group may assume uniformity: and where single plants are used in prominent positions, the most robust look the boldest and best. There is one among the weaker growers deserving of special mention (R. Gibsoni), which has leaves and stem as darkly-coloured and rich-looking as Iresine or Dell's beet; and, if planted with an edging of Abutilon Thompsoni, the contrast between the two is most pleasing, as they associate and look well together. As these castor oils are gross feeding plants, the soil should be specially prepared for them by being trenched or deeply dug, and at the same time heavily manured with rotten dung; and if this is done, they will develop magnificent leaves, and have a shapely appearance the whole of the summer. Many make mistakes with ricinus in sowing them too soon, and starving the plants at first starting; for if they become drawn and checked then, they run up with weak naked stems instead of being furnished with foliage below. As the seeds germinate so quickly, and the plants grow so fast, the middle or end of April is quiet time enough to sow, for it is not safe to plant out till the first week in June, and they get to a large size in a month or six weeks, if well treated and nursed on in heat. Before planting out it is necessary to harden them by gradual exposure, and directly they are in the beds they should be staked and securely tied, or the wind will break and destroy them.—D.—*Field.*

INFLUENCE OF THE STOCK ON THE GRAFT, AND OF THE GRAFT ON THE STOCK.

Some contest this influence. Very lately my friend Alphonse Karr has cited an example, that of hybrid perpetual rose flowering better when grafted on the common China rose than on the briar. In my opinion that influence is general, although not always perceptible. Let those who have doubts make an experiment. Let them plant two wild briars, like those used for standard roses, near one another, graft one of them with a tea rose, and let the other grow at random. After three or four years they will find that the grafted one has scarcely grown thicker, and that the one left to itself has nearly doubled in circumference; and perhaps the grafted one has died. Who does not know that pears are grafted on the quince to obtain pyramidal forms, growth not too vigorous, and in consequence earlier fruit? Let those who are not acquainted with this matter graft the same variety of pears on a quince stock and on a seedling pear of the same age, and they will soon perceive that the latter is by far the more vigorous. I had in the severe winter of 1871 a sad experience; all the pear trees in my garden grafted on quinces were killed by the hard frost, while those on pear stocks survived. Why do tea roses, and particularly the more delicate varieties, acquire more vigour when grafted on the seedling briar than on their own roots?—JEAN SISLEY, Monplaisir, Lyons.—*Field.*

TENNYSON AND TREES.

It is interesting to notice the frequency with which our common forest trees are mentioned in the writings of Mr. Tennyson. To the Oak many felicitous epithets are applied, the most remarkable of them, perhaps, being "gouty," which is used,—playfully of course,—in "Amphion." Everyone remembers the Oak—

"So hollow, huge, and old,
It looked a tower of ruined masonwork,"

before which the fair but false-hearted Vivien lay at the feet of the great enchanter; and also the tree described in that lightest and brightest and most airily-sweet of poems, "The Talking Oak."

The Beech, despite its inexpressible beauty, not only when clad in freshest summer green, but also in autumn, when its leaves are dyed a million glorious colours, has been somewhat neglected by the Laureate, as well as by most of our poets; but in "Edwin Morris" we read of a thought

"That like a purple beech among the greens
Looked out of place."

The Ash has received more attention. In "The Gardener's Daughter" Juliet's hair is said to be black

"As ash-buds in the front of March;"

and in "The Princess" we find the following lines:—

"Why lingereth she to clothe her heart with love,
Delaying, as the tender ash delays,
To clothe herself when all the woods are green."

In "The Miller's Daughter" we read of

"Gummy chestnut buds
All glistening to the breezy blue";

in "In Memoriam" of the Sycamore's "breadth and height" of foliage; and in "Amphion" of the "Birch's fragrant hair."

The joyful Elm is spoken of as "full foliaged"; and notice is taken of

"The moan of doves in immemorial elms
And murmur of innumerable bees";

while the lines—

"Witch-elm, that counter-change the floor
Of this flat lawn with dusk and bright,"

show that the poet recognizes the beauty of the less stately Wych or Scotch Elm. The dark and gloomy Yew is noticed almost as frequently as in the writings of Wordsworth. Probably the finest lines ever written on what is pre-eminently the "tree of bitter gall and ebon sad" * form section 2 of "In Memoriam."—FRANK MILLER.—*Journal of Forestry.*

* Spenser.

ANALYSIS OF MANURES.

During a course of lectures at Aberdeen, Mr. Jamieson F.I.C., dealt very fully with the subject of the analyses of manures, which at present, he declared, have neither the essential of accuracy, nor the virtue of simplicity. He stated the errors arose from incapacity, accidents, and unequal samples; but outside these inaccurate processes were used. Analyses and phosphates were usually "high," and he quoted a series of experiments to show that the inaccuracy was generally from 1 to 3 per cent, and he suggested that, in their own interests, farmers should insist on their phosphatic manures being analysed by the Molybdenum method, and checked by the Uranium method. Phosphate of lime was the only useful phosphate as a manure; but in analyses, phosphates of iron and alumina were included, and usually went as high as 5 per cent. These should be stated separately. To make his meaning clear, he showed that 310lb of insoluble phosphate of lime mixed with sulphuric acid makes a quantity of gypsum, and only 234lb of soluble phosphate; but credit is usually given by the chemist for 310lb., there being here an error of 76lb. Other errors similar in principle arose in denominating the essential ingredient in phosphate, and in using the term ammonia when it was necessary only to determine the amount of nitrogen, and in using the word potash instead of potassium. After explaning his views on these matters. Mr. Jamieson urged that we ought to have a uniform system of stating an analysis that shall be intelligible. He recommends that the ordinary form of analysis shall be treated in the following manner: The useless matter—viz., the water, the sand, the organic matter, and the alkaline salts—shall be first struck out. Then a circle should be put round the matter of little value, viz., the magnesia and lime, and a cross put against the probably injurious matter, viz., sulphuric acid. You would than be able finally to determine how much there is of the three useful elements, viz., nitrogen, phosphorus, and potassium. For this purpose he recommended the following practice:

To Change	To	Multiply by
Ammonia	Nitrogen	0·823
Sulphate of ammonia	„	0·212
Dry potash	Potassium	0·83
Wet potash	„	0·7
Sulphate of potash	„	0·45
Insoluble phosphate of lime	Phosphorous	0·2
Soluble ditto ditto	„	0·265
Biphosphate of lime	„	0·313
Phosphoric anhydride	„	0·44
Phosphoric acid	„	0·32

But, as even with this there would still be to some extent a difficulty in farmers knowing what the actual value of the manure was, and as to the kind of potash or phosphorus meant, Mr. Jamieson urged that all analyses of maures should be stated in the following manner:

- Useful matter
  - Nitrogen
  - Phosphorus, as soluble phosphate of lime.
  - Phosphorus, as insolnble phosphate of lime.
  - Potassium.
- Matter of little value.
  - Lime.
  - Magnesia
- Matter probably injurious ..... Sulphuric acid
- Useless matter..
  - Water.
  - Organic matter.
  - Sand.
  - Alkaline salts
  - Phosphorns as phosphate of iron and alumina.

Such a form as this would give farmers a fairly intelligible idea as to the manure they were purchasing, and on the ground of both simplicity and greater accuracy, it was recommended to their attention.—*Field.*

FRUIT AND VEGETABLE CULTIVATION IN ITALY.

In a report on the fruit cultivation in Italy, it is stated that this branch of culture cannot be said to be skilfully managed, and its results are rendered uncertain by the great variety of the climate and the predominance of high winds. Mild winters are often followed by hard weather in spring, which destroys the buds; but the supply of fruit can generally be kept up from other parts which have not suffered. In

a good year Plums, Peaches, and Cherries are sold in Naples at 1*d.* to 1½*d.* per kilogramme. Quantity prevails over quality, as the natives prefer to eat four bad Peaches rather than one good one at the same price. The fertility of the soil causes a copious production in spite of the bad system of cultivation, in which the training and trimming of the trees is almost entirely ignored. The exportation of both fresh and tinned fruit and vegetables is daily increasing. New and even superior varieties of fruit obtain no sale in the local markets, the populace refusing to buy any but the kinds known to them. There is a large export trade in Walnuts, especially from Sorrento, but it has somewhat languished of late in consequence of the exporters having filled up their boxes with inferior sorts so as to satisfy the great demand and obtain a larger profit. Oranges and Lemons are much grown for export. Figs, especially in their fresh state, are enormously consumed in Naples. There are twenty-three varieties known, and no disease has hitherto attacked the Fig. The various modes of its cultivation are very interesting, and the same may be said with regard to the Orange and Lemon, so extensively cultivated at Sorrento. These trees are subject to no serious disease, and fear only the cold, against which, however, no precautious are taken in this part of Italy. Land on which Oranges grow lets at £27 per acre, and sells at an even higher comparative rate since it is small in extent and there are very many would-be purchasers. All the Oranges exported are measured by being passed through through a ring, and only those are packed which are of an uniform size. Increased facilities of railway transport have reduced the retail price of the fruit in distant northern countries from 1 franc to less than 20 centimes. Citric acid has, hitherto, not been manufactured in Italy, the Lemon juice being sent in casks to England, but it is intended to start this industry at Ischia. Olives are extensively cultivated in the districts of Sorrento and Castellamare, and the oil produced is of excellent quality. Want of skill and attention is again manifest in this branch of agriculture. The cultivation is likely to remain stationary on account of the lack of new ground available for the purpose. Grapes are grown in all parts of the provinces both for wine making and for the table. Thirty or forty varieties of Vine are grown promiscuously, whereas a few choice kinds would produce better results. No real improvement can be expected until selection becomes general and the cultivation of inferior Vines is abandoned. The system of training Vines in festoons from high poles or trees, which prevails in the South of Italy, is an irrational one; the Grapes ripen badly and make inferior wines, but on the other hand room is left on the ground for growing vegetable produce, and the Poplars which are so much used for supporting the Vines furnish valuable fuel in considerable quantity. Four Vines are attached to each tree to a height of 4 metres. No rearing-houses for Vines have yet been built, and the want of them is much felt. The Vine diseases most prevalent are the oidium, anthracnosis, and torula. Vine leaves are much used as food for cattle. Not less than 141 varieties of Grapes grow in the province of Naples alone. Tomatos are grown and consumed to a prodigious amount, both fresh and as sauce for maccaroni. They are a favourite food with all classes. This cultivation is constantly assuming larger proportions on account of the extensive exportation of the fruits. Amongst other produce, of which the cultivation is important, may be mentioned Water Melons, Artichokes, Peas, Cauliflowers of huge size, Strawberries, and all kinds of early fruit and vegetables for export. There is plenty of room for improvement in the tillage of gardens and kitchen gardens. No schools of botany exist, and ignorance holds undisputed sway. Hemp is better understood, and yields remunerative crops.—*Gardeners' Chronicle.*

THE BITTER PRINCIPLE OF HYMENODICTYON EXCELSUM.

BY W. A. N. NAYLOR.

The paper is printed on p. 961, and gave rise to the following discussion :—

The PRESIDENT said he was sure it would be the desire of the meeting that Mr. Naylor might shortly find an opportunity of completing his investigations on this subject.

Professor BENTLEY said that this question was invested with interest now in consequence of the "euprea" barks and other barks obtained from allied plants, which were formerly placed among the cinchonas, having yielded a certain amount of cinchona alkaloids. At the first blush a botanist would naturally expect that *Hymenodictyon excelsum* would have yielded some of the alkaloids of cinchona, since the genus *Hymenodictyon* was formerly included in the genus *Cinchona*, and this plant was the *Cinchona excelsa* of Roxburgh. One would naturally expect to find paricine or some allied alkaloid. The first plant in which paricine was discovered, as far back as 1845, was a rubiaceous plant, namely the *Buena hexandra*. The interest of paricine being found in *Hymenodictyon excelsum* was still further brought out by the fact that it had been found in red bark together with quinamine. Therefore the investigation of substances derived from plants which had been within a comparatively few years disassociated from the cinchonas became a matter of great interest, and he looked forward with interest to the confirmation or otherwise of Mr. Naylor's present results by his further investigations.

Mr. HOLMES said that his name had been mentioned by the author in connection with this bark, but he should like to disclaim any thanks with regard to the matter. The bark had been sent to him by Dr. Dymock, of Bombay, a gentleman who had in a most disinterested manner contributed very largely to the museum on various occasions. Dr. Dymock had kindly promised to complete the collection of Indian drugs for the museum.

Dr. ONDAATJE, referring to the virtues of *Hymenodictyon excelsum* as a febrifuge, said that he was in India many years back, when Sir William O'Shaughnessy was compiling his first book on Indian drugs, the 'Bengal Dispensatory,' and this drug was then tried in the hospitals of the Medical College and found to be most valuable. In mild cases of fever it was almost equal to the cinchona bark. There was another species almost as efficacious as the *Hymenodictyon excelsum*. He believed that it was the *H. laxiflorum*.

Mr. LUFF wished to ask Mr. Naylor whether heat was employed in drying the pasty mixture of the powdered bark. He would suggest that Mr. Naylor, on resuming his investigations, should extract the alkaloid under somewhat different conditions. According to his (Mr. Luff's) experience of alkaloid work, Mr. Naylor had employed almost the very conditions which were most likely to bring about a decomposition of the alkaloid, namely, in the first place, contact with a fixed alkali, lime; in the second place, percolation with boiling or hot alcohol; in the third place, contact with a strong inorganic acid—sulphuric acid—during the distillation; and in the next place precipitation with a fixed alkali, caustic soda. In his experience those conditions were likely to produce that destruction of the alkaloid which was generally spoken of in chemical phraseology as saponification. This change consisted of a decomposition of the alkaloid into another alkaloid of a lower molecular weight and an acid. Probably the reason why Mr. Naylor obtained a resinous mass, and failed to get a crystallizable alkaloid or crystallizable salts, was that he had brought about this kind of decomposition. All the different kinds of alkaloids which Dr. Wright and he had worked upon were decomposed by contact with even warm alcohol, by contact with any of the alkalies, and by contact with any of the mineral acids. He would suggest that Mr. Naylor should percolate the bark with alcohol acidified with tartaric acid, for an organic acid produced scarcely any saponification, and avoid precipitation with a strong alkali such as caustic soda or potash. Assuming that the alkaloid present with the bark was paricine, which seemed probable, Mr. Naylor's experiments would point to an actual decomposition or saponification of the alkaloid, for the general result of saponification was that, whilst the carbon percentage of the alkaloid remained the same, the hydrogen percentage was increased; and this Mr. Naylor's figures showed.

Mr. GERRARD differed somewhat from the statement which had just been made by Mr. Luff, especially with regard to the use of lime as the means of liberating alkaloids under certain conditions. He thought that the process employed by Mr. Naylor was admirably suited for the purpose where an alkaloidal body was in combination with an acid of the tannic acid series. Lime lent itself most

readily to combinations with acids of that series, and also with many of the colouring matters. Let any one take a sample of cinchona bark, and mix it with potash soda, or ammonia, and another portion and mix it with lime, and prepare a tincture from each mixture; the difference of colouring of the two mixtures would be astonishing. Of course an operator conducting an experiment with lime and a bark would take care that he did not carry his temperature too high. It was possible to exhaust cinchona bark with lime and alcohol at a normal temperature, provided that the bark and the lime were in a proper state of division. He did not say that lime was adapted all round under all circumstances; but under certain circumstances it was the best agent. Especially was it the best thing for beberine. He had lately had a bark sent to him from the west coast of Africa, and he had experimented upon it with various alkalies, but the found lime the best of all. He should like to ask Mr. Naylor whether he prepared the hydrobromide or the phosphate of the alkaloid. Those salts usually yielded themselves very readily to crystallization, and as a rule they were insoluble in cold alcohol, but they dissolved readily in hot alcohol, from which they were generally deposited upon cooling in a crystalline from. That was, in his opinion, one of the best methods of obtaining a pure crystalline salt of an alkaloid. He should like to know what quantity of bark Mr. Naylor operated upon, as the quantity made a considerable difference in the investigation It was not possible to carry out a thoroughly exhaustive investigation with a small quantity; from 7 to 14 pounds were needed for a full investigation.

Mr. LUFF remarked that Mr. Gerrard had not brought forward any experimental evidence that lime did not bring about the decomposition which he (Mr. Luff) had mentioned.

Mr. TANNER said he should like to ask whether Mr. Naylor had examined the liquid from which the precipitate was obtained, and whether he concluded that by the precipitation of the body which appeared to be allied to paricine he had separated all the alkaloidal constituents. If not, Mr. Naylor's results and those obtained by Mr. Broughton might be brought into accordance. It was known that when alkaloids were precipitated with caustic soda or potash, the residual liquor might contain another body, even æsculin, or the product æsculetin. With regard to the non-crystallizability of the alkaloid, he should like to ask what solvents Mr. Naylor employed, for it was known that in some cases the addition of a body having a less solvent action on the alkaloid than the one in which it was dissolved would determine crystallization.

Mr. NAYLOR, in reply, said in reference to the remarks of Mr. Luff, that he did not think that any process which could be devised would be suitable for the extraction of an alkaloid in every instance. Had he not been pretty certain from preliminary investigations that the alkaloid in question was very closely allied to beberine on the one hand, and to quinine on the other, and further, had he not found the colouring matter somewhat troublesome, he certainly should not have employed such a process as the lime process. That process was by no means original. Not only was it largely employed for the extraction of quinine from cinchona barks, but it was the process which Dr. Hesse had himself made use of for the extraction of paricine. He thoroughly agreed with what Mr. Gerrard had said as to the use of lime, and he only needed to emphasize his remarks on that point. Oxalic acid was perhaps about as serviceable an acid as could be employed for the extraction in this case. It extracted the alkaloid with probably the minimum amount of colouring matter, and it might be advisable to employ a weak solution of oxalic acid; but decomposition took place very largely in the heating of the body afterwards. In reply to Mr. Gerrard, he might state that he did not prepare the hydrobromide, but he did prepare the phosphate, though he did not succeed in getting it to crystallize. The quantity of bark that he worked upon was 300 grams. The bark was tested for æsculin, but that body was not found. The solvents employed were benzol, chloroform, ether, petroleum spirit, acetic ether, organic acids and mineral acids. As to temperature, he had employed various temperatures ranging form 60° to 120°; and with regard to time, the periods had varied from very short ones to periods of four or five days, with a temperature of 110° F. It was well known that paricine had not yet been obtained in the crystalline condition. He wished it to be distinctly understood that he did not state that the body which he had obtained was paricine; that point remained for further investigation.

A vote of thanks to Mr. Naylor was then passed.—*Pharmaceutical Journal.*

VICTORIA PLANTERS' ASSOCIATION, NATAL.

TREE-PLANTING AND RAINFALL.

Mr. Wilkinson's paper, as follows, was then read:—

Tree-planting in its relation to the rainfall of the country, and the kinds of trees most adapted to our coast climate.

The subject of the influence of trees on rainfall has been a good deal written on, and in a series of articles published by Mr. A Fryer in the *Sugar Cane*, the subject has been very ably and exhaustively treated. Any one reading these articles can come, I think, only to one conclusion. I propose in this paper to make a few extracts from them, and must refer any one requiring more information to Mr. Fryer's papers in vols. 4, 5 and 6 of the *Sugar Cane*. In many countries and districts which once were celebrated for their fertility, agriculture cannot now be carried on at all on account of the diminished rainfall, consequent on denuding the country of forests and bush—for instance Palestine, the northern shores of the Mediterranean, Greece, and parts of Spain. The mountains of Estremadura and Murcix have been stripped of their forests, and there is now no rain there for eight to ten months, which forbids agriculture; while Catalonia and Valencia are covered with wood, and possess a moist and productive soil. Professor Lindley observes of Mauritius: "If this island should in time become barren, it will only undergo the fate which universally attends the destruction or absence of forest in countries exposed to great solar heat." Blanqui says of the Cape Verd Islands: "The terrible droughts which devastate them must be attributed to the destruction of the forests. On the other hand, in South America, there-appearance of forest upon cleared land was followed by a rising of the waters of Lake Tacaragua." Again Blanqui says: "In St. Helena the wooded surface has extended and the rain has increased in proportion. It is now double what it was during the residence of Napoleon." The same authority says: "In Egypt recent plantations have caused rain. The rainfall in Egypt was as low as 12in. a year, but by the planting of some millions of trees by Mahamet Ali the rainfall has been brought up to 40in. This is a quantity at which sugar can be profitably grown, although 50 in. would be better; in some of the more favoured stations in Mauritius the rainfall is over 70in. When the Mormons first settled in Utah they found the district barren; water had to be brought almost incredible distances in wooden pipes; trees were carefully planted and nourished with the water so brought, and now the district may be termed the garden of the world, and is not dependent on water brought a distance, but enjoys a steady rainfall." In Ascension, the re-planting of a mountain caused a spring which had dried up after felling the wood to flow again with its former abundance, the wood having been cut down on the sides of the mountain had dried up the spring at its base. The following is from "Proctor's Light Science":—"We may point out in this place the important connection which exists between the rainfall of a country and the amount of forest land. We notice that in parts of America attention is being paid with marked good results to the influence of forests in encouraging rainfall. We have here an instance in which cause and effect are interchangable. Rain encourages the growth of an abundant vegetation, and abundant vegetation in town aids to produce a state of the superincumbent atmosphere, which encourages the precipitation of rain. The consequence is, that it is very necessary to check, before it is too late, the processes which lead to the gradual destruction of forests. If these processes are continued, and the climate has become excessively dry, it is almost impossible to remedy the mischief, simply because the want of moisture is destructive to the trees which may be planted to encourage rainfall. Thus, there are few processes more difficult (as has been found in parts of Spain and elsewhere) than the change of an arid region into a vegetation covered district. In fact,

if the region is one of great extent, the attempt to effect such a change is a perfectly hopeless one. On the other hand, the contrary process—that is to attempt to change a climate which is too moist into one of less humidity—is in general not attended with much difficulty. A judicious system of clearing nearly always leads to the desired result. It seems to be generally believed that trees produce the following effects:—They increase the amount of rainfall. This they probably effect thus: They lower the temperature, and thus cause the moisture-laden air first to become visible as cloud, and secondly, to be precipitated as rain. They intercept, and as it were, tap the vapour charged winds. They supersede the state of tension and polarisation which exists when a electrified cloud is above them by silently discharging the electricity. The discharge of electricity, as for example in the case of thunder-storms, is generally accompanied by rain. It is well known that a moderate amount of rain falls upon the ocean far away from land, and it may be thought by some that the absence of trees cannot reduce the rainfall to an amount less than the fall at sea, which may be considered the normal fall. That from some cause or other a less amount of rain may fall upon land than sea, is evident from the existence of the rainless districts of North Africa, Mexico and Peru. In order to attract rain it has been shown that the surface must be covered with objects like trees, which produce a diminution of temperature, which can intercept the current of air, and which are good conductors of electricity. The luxuriance of vegetation does not depend on the amount of rainfall, but upon a sufficiency of moisture finding its way to the roots of the plants. A heavy tropical rain of say five inches in a single day produces no more good than a gentle continuous rain of one inch during the same period, as four-fifths of the former rain are carried away by streams into the sea, and some valuable soil with it. Gentle rain is all utilised; every drop sinks into the ground, neither water nor soil is carried away. If the foregoing explanations are correct it will follow that the gentle showers are attracted by trees, and that violent rains will fall whether trees are present or not. But the trees on the slopes of mountains check the fury of the violent rain, prevent the low lands from being flooded, and save the soil from being washed away.

A good deal might be done in affecting the climate for the better, if owners of estates would make up their minds to plant a few hundred trees each year in a belt east and west across the south-west or rainy winds on their boundary lines; it would have a double effect of attracting the vapour-laden clouds and producing moisture, and also check the spread of large fires from one estate to another—letting alone the great value such plantations would prove in a few years, if suitable trees were planted for wagon wood and railway sleepers, the demand for which I anticipate will be great in future years. For any one who has the capital to spare and can afford to wait for a return, I don't know of any investment which would pay better here than tree-planting. Our Government might assist the movement by giving prizes or premiums in each country for the greatest number of hardwood trees planted when two years old, taking good cultivation into consideration; also by taking the present tax off plantations by striking plantations out of the valuations for railway taxes. The great drawback to persons planting trees is, that it takes both time and money, and there is a long time to wait for any return. Now if a scheme could be elaborated for Government to make loans at a low rate of interest to persons for tree-planting in a similar manner to what is done in England for draining land (such loan to be a first charge on an estate), something might be done towards forming extensive plantations, which would have a double economic effect, viz., improve the climate and save money to the colony for the importation of railway sleepers, which no doubt could be grown for less price and of better quality than those imported. Government might also, at the Botanic Gardens, raise suitable trees in quantity from seed, and supply them at cost price to parties requiring them. Few people have the knowledge and time requisite for raising the various kinds of young trees from seed—it is a business in itself and requires great care and attention. In view of future use the last few years I have given a good deal of attention to the kind of trees best adapted to our coast lands and the most economical way of planting out. Scarcely any of the European forest trees are suitable to the coast lands. The oak makes a good shade tree, but it is of slow growth. For forming plantations rapidly the gums, or *Eucalypti* of Australia, rank first, and as there are over 50 varieties now growing in the colony there is plenty of choice. The blue gum and stringy bark, which grow so well at Maritzburg and beyond, have the great drawback of being destroyed by the white ants. Next to the gums is the blackwood of Tasmania, *Acacia Melanoxylon*. It is a straight-growing tree of rapid growth; the wood is very hard when seasoned, and is suitable for wagon wood, furniture, and railway sleepers. The blackwood has one very valuable property, it will grow well on waste stony places if only a pit is made in the stone to start it in, and it ratoons well, that is grows up again from the roots into fine straight poles when cut down, thus rendering replanting unnecessary. The blackwood must not be confounded with the black wattle; the wattles don't thrive well on the coast, they die away after 5 or 6 years, and are only fit for firewood. The *Casvarina* grows well, being a tropical tree; it is straight and hard, but white ants are rather fond of it; it is a fine tree for attracting rain-clouds from its numerous points. It has been found good for that purpose in Mauritius, where I hear hundreds of acres have been planted with it; it is there called *Felou*. The silver oak or *Grevillia* does well and grows rapidly; but I do not know if the timber is of much value. But the tree of most value to us, if we could get it to grow, would be the pitch pine of the Southern States of America. This pine grows in a similar latitude to Natal; forests of it extend for hundreds of miles, from Savannah across Georgia and Alabama to Mobile. The wood of this tree is all that can be wished for building purposes; it is also good for resisting white ants where growing; for fuel it burns like a torch. There is a difficulty in raising the young plant from seed, but when once over the first year, and planted out, they run up rapidly and are handsome trees; the difficulty at first can be overcome by care and attention. The pitch pine grows best in America in red sandy soil similar to our Berea soil. I must not forget the bamboo, one of the most valuable plants for our watercourses and river banks. In a semi-tropical climate it is invaluable, both for fuel, building coolie houses, fencing, &c. If planted along the watercourses, it preserves the banks from being washed away, and the water from being evaporated; it is very ornamental, easily propagated by cuttings like cane in the spring from last year's shoots; and it is in great demand for building houses. In forming plantations, I would plant these trees out in rows 9 feet apart, or about 500 trees to the acre (allowing for a few misses) in rows both ways, so that a small one-horse plough can be run through each way; and I would put a row of mealies between the trees for the first two years. This would ensure proper cultivation of the trees, and the mealies would pay for the cultivation. It is of little use planting trees in this climate unless you cultivate them well, and keep them free from weeds. What the Mormons have done in Utah to improve the climate for agriculture can surely be done by English colonists in Victoria Country, Natal. The Mormons went to Utah and found it a desert; they have made it one of the gardens of the world. But I am afraid if we go on here as we have been doing this last year, cutting down so much bush and planting no trees, we shall reverse that picture; so let us endeavour to do something to remedy the evil before it is too late. This paper has extended to much greater length than I had intended it, but to treat the subject of the loss of rainfall and its remedy in its various aspects I could not well make it shorter; but I hope it may have the effect of drawing your attention to the very important subject of which it treats.

Mr. Garland said that he had found in the first two years he was in the country that he was able to get over the Umgeni, he walked across the Great Umhlanga dry shod, and all the water in the rivers was collected in pools. In 1850 and 1851 the rainfall was so inconsiderable that the Great Umhlanga was so empty that water to drink could not be obtained, and he remembered trekking up and down to find water for that purpose. That was before any bush was stripped off or trees cut down, so that there were times when droughts occurred. He did not dispute the principle that the denudation of forests

decreased the rainfall, he simply stated that droughts were known. He had heard from one old settler that there was one before that, and tradition said that there were droughts before they came to the country greater than any which had been seen since.—*Natal Mercury.*

CULTIVATION OF CINCHONAS.

The very interesting series of Jamaica cinchona barks, accompanied by leaves, flowers, fruits and seeds of the plants from which they had been taken, which attracted the attention of visitors to the last Evening Meeting of the Pharmaceutical Society, supplemented as it has since been by an even more extensive series from the Indian Government plantations at Ootacamund, which will be shown on Wednesday evening next, will contribute to a realization of the great importance that the experiments in cinchona cultivation in different parts of the world are now assuming towards pharmacists or consumers of bark. It is indeed a matter for congratulation that the authorities at the Indian and Colonial Offices have complied so liberally with the request of the Council of the Pharmaceutical Society, that typical specimens grown in the Government plantations should be made accessible to the inspection of British pharmacists by being placed in the Society's Museum, especially as they are accompanied by useful information as to their history and characters, such as has been furnished by Mr. Morris. Whilst the subject is thus somewhat prominently under notice, it will be opportune to quote from two official reports that have just been issued some statements bearing upon cinchona cultivation in India and Jamaica.

From the new Report on the Trade of British India we learn that the exports of cinchona bark from that country during the year 1881-82 showed a considerable decline as compared with the previous year, the quantity being only 428,497 pounds against 699,258 pounds in the previous year, the fall in value being from R7,24,705 to R4,58,340. This decline, however, does not appear to be attributable to any decrease in the production of the plantations, but to the fall of price in the European market caused by the enormous importations of cuprea bark from South America. Indeed the Collector of Customs at Calcutta expressly states that, if necessary, there could have been larger shipments made than in the preceding year, the trees not having been barked in consequence of the lowness of price. It must not be assumed, however, that the figure reached was therefore one below the point at which cinchona cultivation can be carried on in India profitably; for the bark was simply withheld in expectation of a rise in the market. But should the decline in value prove permanent, the Report says there can be no reason to doubt that the industry is one which has a very hopeful future, notwithstanding it may have to compete with importations from South America. The bark is exported almost exclusively from Calcutta and Madras, a very small quantity being sent from British Burmah. The quantity exported from Calcutta, which is said to represent almost entirely the exports of one company in the Darjeeling district, amounted in 1881-82 to 249,691 pounds, valued at R1,86,795; the exports from Madras amounted to 178,467 pounds, valued at R2,71,195. These figures show that the average price of the bark shipped from Calcutta was very much below that shipped from Madras.

It is interesting to observe in the face of the foregoing figures, suggesting an accumulation of bark in the country, that the imports of quinine rose during the same time enormously, having amounted 10,615 pounds, valued at R9,98,631, in 1881-82, against 3,964 pounds, valued at R4,29,515, in 1880-81. As these figures show that the large increase in the quantity of quinine imported was accompanied by a considerable fall in price, it is probable that both the decrease in exports of bark and the increase in imports of quinine were to a considerable extent due to the disturbing influence of the enormous supply of cuprea bark thrown upon the market as raw material. The figures, however, have a further significance, since they show that a low-priced quinine is capable of driving all its competitors out of the field. In the previous report it had been remarked that the "cinchona alkaloid" had been largely used in preference to quinine, and to this preference was attributed some falling-off in the imports of quinine; but the larger consumption of the mixed alkaloids would now appear to have been based rather upon economical considerations. The increased demand for quinine may, however, have been due to some extent to the fact that although the general health of the country was fairly good during the year, there were severe outbreaks of malarious fever in certain districts in Bengal; whilst in parts of Northern India also fever was more than usually prevalent.

A Supplement to the *Jamaica Gazette* of the 22nd ult. contains the report of the Director of Public Gardens and Plantations in Jamaica for the year ending September 30, 1882. In this report Mr. Morris states definitely that the purpose of the Government in establishing cinchona plantations in Jamaica,—namely, to show that cinchona barks of good quality could be produced in the island, and that cinchona planting, as an enterprise in private hands, possesses all the elements of a remunerative industry,—has been attained, these points having been demonstrated by the returns from the sale of Jamaica-grown barks during the last three years. It is therefore proposed henceforth to devote the chief attention in the Government plantations to the introduction and cultivation, on a small scale, of all new and rich kinds of cinchonas, with a view to establishing them as far as possible in the island, and to carrying on experimental and scientific work in connection with the industry, such as is not likely at present to be undertaken by private individuals. The extent to which Mr. Morris has succeeded in impressing upon others his conviction as to the remunerativeness of cinchona cultivation is shown by the fact that during the year the sales from the Government nurseries to private planters amounted to 372 ounces of seeds, 77,961 plants and 362,250 seedlings of various species of cinchona, *C. officinalis* appearing to be the one most in demand. One shipment only of bark to Europe was made during the year, and this consisted for the most part of "thinnings" or "prunings" from two plantations, rendered necessary by the too abundant growth of established trees and self-sown seedlings. Notwithstanding, however, that the consignment, amounting to 21,512 pounds, consisted consequently principally of twig and broken bark, and the somewhat unfavourable condition of the market, the results were very satisfactory, the net amount realized being £2,419 5*s.* 7*d.*, the prospective estimate having only been £2,000. As compared with consignments from other countries the prices obtained for this Jamaica-grown bark were very encouraging. The highest price, 8*s.* per pound, was paid for 248 pounds of root bark of *C. officinalis*, taken from trees eight or nine years old, whilst a large package of stem bark realized 4*s.* 11*d.* per pound. The largest parcels were 7,844 pounds of "small branch" bark which fetched 3*s.* per pound, and 6,151 pounds of twig bark, derived from young shoots and saplings, probably not more than a year and a half old, which realized 1*s* 5*d.* per pound. Since the actual cost of barking, curing and shipping amounted to only about 7½*d.* per pound, it is evident that even these young growths yielded a fair margin of profit.—*Pharmaceutical Journal.*

CULTIVATION OF CINCHONA IN JAMAICA.*

NOTES ON SPECIMENS OF CINCHONA SENT TO THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN FROM THE GOVERNMENT PLANTATIONS.

BY D. MORRIS, M.A.,

Director of Public Gardens and Plantations in Jamaica.

No. 1.—*Cinchona officinalis*, of the ordinary type of the Government plantations, Jamaica. Specimens of leaves, flowers, fruit and seed. Three kinds of bark, viz., root, stem and twigs. All the specimens with the exception of the seeds (in a separate packet) have been taken from the same tree, so that botanical specimens as well as samples of bark, are exactly identical.

With reference to this species of cinchona in Jamaica the following extract from official reports and letters from Mr. John Eliot Howard, F.R.S., on similar specimens will be of interest.

"*Cinchona officinalis* of the Jamaica plantations.—The average price per pound on all qualities, viz., root, stem

* Read at an Evening Meeting of the Pharmaceutical Society, March 7, 1883.

and branch bark, 6*s.* 7*d.*; highest price realized, 10*s.* 1*d.* per pound for root bark; lowest price realized, 2*s* 3*d.* per pound for twig bark."

The tree from which the specimens were taken was about nine years old, and growing at an elevation of 5,500 feet. Mr. Howard's analysis of the trunk bark is as follows:—

Quinine alkaloid . .	5·18	=Quinine Sulphate . .	6·95
Cinchonidine	0·22		
Cinchonine	0·01		
Quinidine	0·15		

Mr. Howard adds:—"This bark does not require many observations, as the price per pound agrees with the appearance of the bark and with the analysis in showing that it is good *Cinchona officinalis*, perhaps of slightly varying forms."

No. 2.—*Cinchona Succirubra*, of the ordinary type of the Government plantations, Jamaica. Specimens of leaves, flowers, fruit, seed and three kinds of bark, viz., root, stem and twigs; all the specimens have been taken from the same tree.

"*Cinchona succirubra* of Jamaica plantations. Average price per pound on all qualities, viz., root, stem, and branch bark, 4*s.*; highest price realized 5*s.* 7*d.* per pound for root bark; lowest price realized 1*s.* 3d. per pound for twig bark." Specimens sent from trees nine years old, growing at an elevation of 5,000 feet. Mr. Howard reports on this bark as follows:—"Very good and true *Cinchona succirubra*, agreeing well with my specimens from South Americe. It is a *sub-pubescent* form."

No. 3.—*Cinchona hybrid* of the Government plantations, Jamaica. Specimens of leaves, flowers, fruit, seed and three kinds of bark, viz., root, stem and twigs. All the specimens have been taken from the same tree. Supposed to be a hybrid from between *Cinchona succirubra* and *Cinchona officinalis*. Up to 1879 it was considered by Mr. Thompson to be *Cinchona Calisaya*. Average price per pound on all qualities, viz., root, stem and branch bark, 6*s.* 1¾*d.*; highest price realized 7*s.* 9*d.* per pound for trunk bark; lowest price realized 4*s.* 6*d.* per pound also for trunk bark. The specimens taken from a tree nine years old, growing at an elevation of 5,300 feet. Mr. Howard's analysis of trunk bark is as follows:—

Quinine alkaloid . .	6·00	=Quinine sulphate . .	8·00
Cinchonidine	0·73		
Cinchonine	0·10		
Quinidine	0·03		

Mr. Howard adds "What proof is there that this is a hybrid? What connection with Calisaya? It is an excellent bark, resembles true *Cinchona officinalis*, var. *Uritusinga*." In another communication Mr. Howard remarks, "It is evident that the so-called 'hybrid' No. 4, if only it is a free grower, must be about the most valuable of all the sorts. The price obtained in commerce does not seem proportional to its value; but possibly, as remarked before, it may be an exceptionally fine specimen. So far as I can judge by the botanical specimens it is a true form of *Cinchona officinalis*."

With regard to the above remarks on this "hybrid" form, I would mention that although in single specimens of leaves, flowers, etc., it is almost impossible to decide its hybridity, yet on the plantations, where all gradations may be distinguished from among these trees, from almost the pure *succirubra* type to almost the pure *officinalis*, there can be no doubt of their origin. Again, when seed of this kind was sent to Kew the seedlings and plants were pronounced of a decidedly "hybrid" character; and, lastly, although following Mr. Thompson's classification, I shipped the bark at first to the London market as "Calisaya?", the brokers in their report drew my attention to it and remarked, "It is not pure yellow bark, but supposed to be a hybrid with *succirubra*." It is nevertheless gratifying to find that this bark is of so valuable a character, and as it is a free grower at lower elevations, steps are being taken to propagate it for general distribution. According to the analysis of the specimen bark sent to Mr. Howard its market value would not fall far short of 14*s.* per pound.

No. 4.—*Cinchona Calisaya* of the Government Plantations, Jamaica. Specimens of leaves, flowers, fruit, seed and three kinds of bark, viz., root, stem and twigs. All the specimens have been taken from the same tree. These trees are about 9 or 10 feet high at five or six years old; they were formerly included under *Cinchona officinalis*. Their compact hardy habit and early maturing render them very suitable for steep slopes. Mr. Howard's analysis of trunk bark is as follows:—

Quinine alkaloid . . .	3·70	=Quinine sulphate . .	4·93
Chinchonidine	0·60		
Cinchonine	·35		
Quinidine	·05		

Mr. Howard adds "these trees appear to me to be true to the Calisaya type and form a valuable portion of the plantations. I should not think they belong to either the Josephiana or the Ledgeriana form, but that the exact variety is perhaps not yet published. In the meantime it might be well to call them *Cinchona Calisaya* simply. There is no appearance of 'hybridity' nor any resemblance to the Loxa (officinalis) barks."

No. 5.—*Cinchona Ledgeriana*. Specimens of the leaves and flowers from one of three plants (the broad-leaved form) of this species sent out by Mr. John Eliot Howard, F.R.S., through the Royal Gardens, Kew, in 1880. For description and plate of the original of these plants, see *Gardeners' Chornicle*, 1880, vol. 12, p. 457. The plant from which the specimens were taken was 6 feet high: some trunk bark is sent herewith.

No. 6.—Specimens of leaves and flowers of a tree supposed to be *Cinchona Micrantha*, not determined.—*Pharmaceutical Journal.*

ON THE DISTRIBUTION OF FORESTS IN INDIA.*

BY DIETRICH BRANDIS, PH. D.

From an able paper by the late head of the Indian Forest Department republished in the *Indian Forester*, we quote a few important passages:—

In all countries the character of forest vegetation mainly depends on soil, climate, and the action of man. In India the greater or less degree of moisture is perhaps the most important element in this respect. Moisture and rainfall are not identical terms. Dew and the aqueous vapour, dissolved in the atmosphere, or the water derived from the overflow of rivers and from percolation, are sources of moisture as important for the maintenance of arborescent vegetation as the fall of rain and snow. It would greatly facilitate the labours of the forester, and of the botanist who inquires after the geographical distribution of forest trees, if the amount of atmospheric moisture and the formation of dew during the seasons of the year in different parts of India had been sufficiently studied; but, in the present state of our knowledge, we must be satisfied with dividing India into regions and zones according to the more or less heavy rainfall during the year.

Really thriving forests are only found where the fall exceeds 40 inches, and rich luxuriant vegetation is limited to those belts which have a much higher rainfall. It must be borne in mind that the annual mean temperature of Central Europe ranges between 45° and 60°, while that of India is as high as 75° to 85°. Under a higher temperature a larger amount of moisture is required to produce rich vegetation. At the same time, in India, the supply of moisture in unequally distributed over the seasons of the year. In most districts the year divides itself into two unequal parts,—a long dry season, and a short rainy season. In most provinces of India the principal rains are summer rains, due to the prevalence during that season of the south-west monsoon, and the most humid regions are those tracts which are fully exposed to the influence of these moist south-westerly winds. In addition to these, there are Christmas or winter rains in Northern India, but they only last a few days, or at the outside a week or two,

* The above has been reprinted from the Transactions of the Scottish Arboricultural Society, 1873, and was sent to us by Mr. Brandis, who stated that he saw no reason to make any alterations at the present time, and we have therefore reproduced it for the benefit of the readers of the *Indian Forester*, few of whom may have had access to the original.

The map has been prepared through the kindness of Mr. G. B. Hennessy, Deputy Surveyor-General, from the one accompanying the original pamphlet, and is an improvement on the latter in many respects.

and are, moreover, extremely uncertain and irregular. On the eastern coast of the peninsula the summer rains are slight, the principal fall coming with north-easterly winds in October and November. But in the greater part of India the dry season lasts from November to May, the rains commencing between May and July, and ending between August and October. In the moister districts the rains commence early and last longer, while in the dry belts there is rain only during two or three months of the year; and in the arid region the rainfall is altogether uncertain.

The temperature during this long dry season is cooler at first and warmer afterwards. The mean temperature of the three months, December, January, and February, generally termed the cool season, ranges between 60° in the Punjab, and 79° in the south of the Peninsula. During these months dew is formed more or less, regularly, and contributes much to the maintenance of vegetation particularly in the dry and arid zones. Radiation is so powerful during this season that frost is not of uncommon occurrence in the plains and lower hills of Northern and a part of Central India. These night frosts have interfered much with the satisfactory progress of the plantations in the Punjab, and as far south as Sukkur on the Indus, in latitude 27° 30′, and the Satpura range in the Central Provinces, in latitude 23°, frost is a serious difficulty in arboriculture. As far south as Calcutta, ice can be made on carefully prepared beds covered with straw, shortly before sunrise on a still, clear morning. The mean temperature of the three months which follow, which are generally called the hot season, is 75° in the Punjab, 85° along the coastline, and 90° in the interior of the Peninsula, and this dry heat, with the hot scorching winds which blow over a great part of India during these months, makes this season extremely trying to vegetation.

With the exception of the extensive evergreen forests of the Himalaya, and the limited tracts of evergeen forests in the plains and lower hills of the humid regions, the great mass of forests in India are deciduous, and they are bare and leafless during the hot season. During this time of the year, the sojourn in the Indian forests is not pleasant. No shade, no protection against the fierce rays of the sun, great scarcity of water in many parts, and a tent or hut with a temperature in its coolest part of 102°,—these are conditions of existence which are not not easily forgotten. Deciduous, however, as applied to trees, is a relative term. The only difference is, that an evergreen tree retains its leaves longer than one which is called deciduous. Thus the spruce and silver-fir retain their needles from seven to eleven years, the Spanish *Pinus pinsapo* and the *Araucaria* retain them even longer, hence the full foliage and the dense shade of these trees. On the other hand, the needles of the Corsican and Austrian fir, (*Pinus laricio*) remain three to four years; and the Scotch fir, with lighter foliage, has needles of two or three years only on its branches. The sál tree (*Shorea robusta*), one of the most important timber trees of India, with strong, hard, heavy wood, which forms extensive forests along the foot of the Himalaya and in the eastern part of Central India, retains its leaves nearly twelve months; the old leaves fall gradually, and the foliage gets thinner and thinner, and until the new flush of leaves breaks out in March or early in April. So that although a sál forest is hot during that time of the year, and there is not much shade, yet the tree is never completely bare. The teak tree, on the other hand, which may be called the king of Indian timber trees, on account of its useful, durable, strong, and yet not very heavy wood, sheds its leaves as early as January, and is leafless for four or five months, though this again depends upon the supply of moisture, for in low humid places the tree often continues green throughout February. Fortunately for foresters in the hot dry provinces of India, there are to be found in most dry deciduous forests one or two kinds which break out in leaf sooner than the others, and I have spent many an hour during the heat of the day under the grateful shade of what we call the forester's friend (*Schleichera*) *trijuga*), a tree remarkable for its extremely heavy wood, the cubic foot weighing, when perfectly dry, over 70 lb., or nearly three times the weight of common deal.

Writing of forest fires, Dr. Brandis traces to their effects which are also most marked in Australia, the general hollowness of trees:—The damage, however, done by them defies calculation. Millions of seeds and seedings are destroyed, trees of all ages are injured, and often killed, the bark is scorched and burned, the wood exposed to the air, dry rot sets in, and the tree gets hollow and useless for timber. One of the most remarkable facts in the working of the Indian forests in the plains and lower hills has been the large proportion of hollow and unsound trees. In many forests one-half, in others three-fourths of the mature trees are hollow. To a certain extent this is due to the old age of the timber felled; but experience elsewhere proves that old age can only account for a small proportion of the hollow and unsound trees. The annual jungle-fires are the principal cause of this mischief. In this respect all deciduous forests in India suffer alike. With regard to reproduction, that this, the growth of seedlings, some trees are better off in this respect than others. Thus the sál tree ripens its seed about the commencement of the rains, after the jungle-fires have passed through the forest. The young plants thus germinate at once in great abundance. The jungle-fires of the coming season kill a good many and cause a large proportion of the others to grow hollow; but in the dense mass of seedlings which clothes the ground under the the parent trees in a sál forest, the damage done is comparatively small. This, to a certain extent, explains how the sál forests are nearly pure, the stronger tree in the matter of reproduction predominating over all the rest. The teak, on the other hand, ripens its seed early in the dry season, the jungle-fires consume large quantities of it; a smaller proportion of seedlings spring up, and these are either killed or cut down to the root year after year by the fires. Meanwhile, the root stock increases in size every year by the action of the shoots, which come up during the rains, and at last, often after the lapse of many years, it produces a shoot strong enough to outlive the fires. Thus what appears a seedling plant of teak is in most cases really a coppice shoot from a thick gnarled root-stock, bearing the scars of successive generations of shoots, which were burned down by the annual fires.

From what has been said, it will be understood that in the plains and lower hills of India the annual repose of arborescent vegetation is not caused by the cold of winter, but mainly by the drought of the hot season. Shortly before the rains set in, or with the early showers which precede the monsoon, most trees clothe themselves with fresh green, and in the arid region, where the periodical summer rains are wanting, the summer floods of the river revive the forest growth on its banks after the long drought of the dry season. In those parts of India which have a heavy monsoon, the temperature is generally somewhat lower during the summer months, June, July, and August, than during the preceding hot season. Thus it is that on the western coast of the peninsula the mean temperature of the hot season is 85°, and that of the three succeeding months, when the sky is overcast with clouds, and the force of the sun's rays is rarely felt, is only between 80° and 82°. On the Burma coast also, in Akyab, Rangoon, and Moulmein, the mean temperature of the monsoon months is somewhat lower than that of the preceding hot season. The relief from the incessant powerful action of the sun's rays, brought about by the storms of the monsoon, and the cloudy and rainy weather which follows, is delightful. It is not the vegetation only which revives; the whole animated nature feels the pleasant change. This relief is denied to the arid region. Here, in the north-west corner of India, the temperature continues to rise higher with the sun, and the result is, that in June, July, and August, the highest mean temperature is found in the arid zone of India. Thus Multan has a mean temperature of 77° during what is termed the hot season in other parts of India, and of 92° during June, July, and August; and at Jacobabad, in Sindh, the mean temperature during these months is as high as 96°. Where, however, sufficient water is supplied by irrigation, these high temperatures stimulate vegetation in a remarkable manner. The station of Jacobabad is a striking example of the effect of water supply in that climate. It was founded in 1844 by General Jacob, in the midst of a barren, treeless desert. A canal was led to it from the Indus, and now the plain is a dense forest of babúl and other trees, upwards of 60 feet high, sheltering the houses and gardens of the inhabitants. A ride of a few miles takes you into the desert which skirts the hills of

Beluchistan, a level plain of splendid, fertile, alluvial soil, but hard, naked, and barren, like a threshing floor, without shrub, herb, or grass, except in the vicinity of the canals, where vegetation is rich and luxuriant.

On the higher mountain ranges of this extensive moist region, forests of pines and other conifers extend from the north-west Himalaya southwards to the mountains of Burma. The deodar has its eastern limit in Kumaon, but there are other coniferous trees, which extend over the eastern part of the Himalaya range. One of the finest of these is *Pinus Kasya*, which is found as far south as the high moutains between the Salween and Sitang rivers in British Burma. These mountains are the seat of a numerous Karen popnlation, formerly an idle, drunken, and lawless race, which, through the teaching of Christianity, brought to them by American missionaries, have become an industrions, sober, and perceful people. Some of their villages are in the midst of these splendid pine forests, and I have often, when coming from the teak forests in the hot valleys of the Salween and Sitang, been refreshed by the delightful fragrance and cool shade of the pine trees on these hills. But, as if to remind the botanist that, though in a pleasant, cool mountain climate, he is within the tropics, and only 19° distant from the equator, there is an underwood of the sago palm (*Cycas*) under the pine trees, and most of the Karen villages are surrounded by the gigantic bamboo, which yields the posts, rafters, walls and floors of their houses. The joints of this bamboo are so large that they are used as water pails and buckets. There is another pine tree in Burma, nearly related to a Japanese species, which grows at a lower elevation in the midst of the dry and hot tropical deciduous forests.

These tropical and sub-tropical pines, however, are not yet of much practical importance. The production of teak timber is the main object which the forester has in view in thore parts of the country. The export of teak timber from Rangoon is of old date; but, under the Burmese rule, the quantity exported never come to any very large amount. When the province of Tenasserim became British in 1826, the Attaran forests, which are situated south of the town of Moulmein, were worked with great energy, and yielded large quantities of excellent timber. The supply from that souree, however, soon dimiuished, and thus the attention of timber traders was directed to the extensive teak-produeing forests beyond the British frontier, on the Salween river and its tributaries, and from that time the importation of foreign timber into Moulmein has steadily increased until within the last few years, when the quantity floated down decreased, mainly because the stock of good timber in the vicinity of the river and its tributaries had gradually become less. Soon after the annexation of Pegu in 1853, the forests of that province were placed under a regular system of administration, and in 1858 this system was extended to the forests in the provinee of Martaban and Tenasserim. The result has been, that without impairing their productiveness, the outturn of the forests in British territory has gradually been raised from an insignificant figure to a very considerable amount; so that within the last five years they have yielded between one-third and one-half of the total quantity of teak timber brought to the principal seaports. The timber trade of the Burma port is not large as compared with that of Canada, yet it is of considerable importance, the export amounting to about 100,000 tons annually, with a value of about £700,000. The forests in the King of Burma's territory; in Siam and the Karenee country, are much more extensive and rich in fine timber than those in onr territory; yet, unless placed under a regular system of management, they will surely be exhausted before long, and on that account we must, to a great extent, look to the forests within British territory for the maintenance of the supply in future. It is satisfactory that the efforts to protect and improve the forests in British Burma have also financially been remunerative. Within the last four years the gross revenue from these forests has fluctuated between £64,700 and £98,400, and the net annual surplns to the State has been between £31,900 and £56,500. The teak tree in Burma, as elsewhere, is found in the dry deciduous woods never forming pure forests, but always growing in company with a large number of bamboos and other trees. Its growth is rapid while young, but slow at a more advanced age. In 1862 I sent a few teak poles, 30 feet long to the great London Exhibition; they had attained that size in two years, in a moist part of the country, on rich soil, and proteeted from fire. On the other hand, the results of researches made regarding the age of mature trees have led us to the conclusion that more than 100 years are required on an average for the teak tree to attain a diameter of 2 feet.

MR. S. TAYLOR, writing in reply to "Crux" relative to Cocoa-nut Fibre and Woodlice, says:—"I use the refuse extensively for plunging Pines and other plants in, and scareely ever see an insect, and having used it for nearly four years in the same houses, I can venture to say it does not harbour woodlice. We have another house in which we use leaves for plunging plants in, and the woodlice breed by the thousand in them; and unless decayed leaves are wanted for soil, t should advise your correspondent to substitute the fibre instead of leaves or manure. Nearly all kinds of cuttings strike rteadily in it."—*Journal of Horticulture.*

ZAPALLO FRUIT.—The fruit of the zapallo, a eucurbitaceous plant of Uruguay, appears to afford a most wholesome food. It is eut up with the saw, because the rind is too hard for a knife to penetrate. It is firm, of a yellow colour, a sweet amylaceous flavour, and slight smell resembling that of the carrot. The most esteemed quality, called rubango, has a ligneous rind of a dark green colour, with orange pulp, and white oily seeds. The relative proportions are:—Seeds 4, pnlp 59, and rind 57. Aecording to M. Sace, the chemical composition is as follows:—Gum, 0·44; sugar, 2·52; stareh, 13·73; fibrine, 0·47; lignose, 0·22; ash, 0·81; water, 81·81; total, 100·0.—*Journal of the Society of Arts.*

LIABILITY OF EXOTIC PLANTS TO DISEASE.—In a review of a report of forest progress in Burma by the *Indian Forester*, we find the following passage:—"*Mahogany* would do well if it were not for the attacks of insects, probably the larva of a beetle. It is stated that "some trees have their terminal shoots eaten off, while others are attacked just above the collar and simply girdled, others again are bored along the whole length of their stem." This liability to injury of introduced species is very eurious, and has caused great havoe amongst Australian trees at the Cape." It will thus be seen that our experience in some parts of Ceylon is not singular as regards the Australian plants, and it must be remembered that einchonas are introduced plants.

THE CATALPA TREE.—Captain Pogson offers some remarks in reference to the "Catalpa tree"—and the desirability of attempting its introduction into India:—I have enclosed a cutting from the *Tasmanian Mail* of the 10th February 1883, which please sumbit to the Council of the Agricultural and Horticultural Society, and if approved published in the Proceedings, so that steps may be taken by the Forest Department, to introduce this valuable tree into India. The Baron von Mueller will no doubt on your requisition send a supply of seeds, which could be tried by the members of the Society, some information as to climate best suited to the Catalpa tree, should be sent you. "Our lands Department, urged by Sir John O'Shannassy, says a Victorian paper, is proposing to introdnce the cultivation of the Catalpa tree. Reports from Baron von Mueller and Mr. Guilfoyle show that these trees are practically imperishable, and are frequently 4½ft. in diameter. Trees of this wood tested after a century of growth have been fonnd to be perfeetly sound, railway rails of it have been used for 48 years without exhibiting wear. Posts 20 years in ground show no decay, and logs lying in swamps, used as bridges for a hundred years, remain unchanged. The wood is light, of a greyish white colour, fine in texture, capable of receiving a brilliant polish, and the bark is tonic stimulant, antiseptic, the honey from the flowers beiug poisonous. It is reeommended for forest glades in sheltered situations, grows 60ft. in height, flowers beautifully, and for mining purposes, especially below water, should prove invaluable. About 250 of these trees have been recently grown at Longerong State Nursery, and their acclimatisation will be watched as an event of national importance."—*Agricultural and Horticultural Society of India.*

CEYLON (WINDSOR FOREST) TEA.

Just as Mr. C. A. Hay is leaving the Windsor Forest tea estate to take charge of Blackwater plantation, Ambagamuwa, there comes the report of the sale of a break of tea made under his care, in the London market, which, we suppose, can be fairly said to be the most satisfactory in prices yet reached for Ceylon tea. Even the Mepitiyakande 4 chests at 2s 8½d can scarcely be placed against a sale of no less than 37 chests of Windsor Forest which realized 2s 4½d per lb. The average of the whole sale is also exceedingly satisfactory and must be gratifying to the proprietor "Logie," while we are pleased to see Mr. Hay (an old Darjeeling planter) coming to the front. Altogether Ceylon tea has made its mark on the London market with unexampled rapidity and there is much encouragement to extend the cultivation of the plant in this island.

TEA PREPARATION.

We extract the following practical notes on "Rolling" from the *Indigo Planters' Gazette*:—

We object to heavy rolling by hand or machine, unless the leaves have been gathered *during* very rainy weather, and they are themselves also overcharged with moisture, in which case it must be resorted to but merely to expel the superfluous water. In all other conditions we maintain that the less pressure is exerted upon them the better and stronger will be the teas. The operation of rolling is simply for the purpose of breaking or bruising the numerous diminutive cells of which the leaves are constructed, in order to induce chemical action to take place, the resultant of which is the product called tea; but how this arises we are unable to state, neither is it of the slightest practical importance to the manufacturer. Old tea planters believed that the rolling was solely for the purpose of extracting the acrid juices from the leaves, but a moment's reflection should convince any one that it is these very juices which are contained in the cells and their interstices that make the tea. To look at the matter in an extreme point of view, supposing the entire fluids were removed from the leaves during manufacture, their would remain nothing but the bare skeletons to be put into the pot, and consequently the boiling water could extract no tea from these suitable for the table. Rolling for a longer time than experience dictates, although lightly, is as detrimental as the converse.

The rolling process during which the leaf cells are broken up, is, of course, absolutely necessary as a preliminary to the important action of "fermentation." The belief is prevalent that the finer if weaker flavour of China teas is due to the fact that the Chinese throw away much of the expressed juice which the manufacturers of Indian and Ceylon teas are careful to have re-absorbed into the rolled tea before it is covered over for the "fermenting" process. Whether scientifically the process, from which germs whether of animal or vegetable origin seem excluded can be regarded as true fermentation or not, is not of practical importance. On the process itself and whether it is too protracted or too limited in time the quality of the tea mainly depends. It is a pity, therefore, that after the learned disquisition on germ fermentation, information was not given as to the varying periods during which tea should be allowed to be heaped under cover, before being fired in wet weather and dry, and the signs indicated of colour, sensation from touch of the hand, etc., indicating ripeness or the reverse. What the writer does is to assume full knowledge on the part of those he wrote to instruct, thus:—

We thus have three phases of fermentation. In all three the casual force is to be found in the *life* existing in cells or seeds or eggs, and the question is—does any such process take place in the manufacture of tea?

The process of rolling expresses the juices of a leaf and among them appears *Tannic acid*. Fire your leaf immediately after it is rolled, and after infusion note favour of liquor and color of out-turn. The liquor, tastes harsh, pungent, and raspy, and is quite unpalatable. It further wants 'body.' Compare this with leaf that has been fired after being just sufficiently *fermented* and then with leaf that has been allowed to 'over-ferment' before being laid on the trays. It is quite unnecessary to enter into particulars, as they are familiar to everyone."

As to "firing" we read:—

The leaf, after having arrived at the proper state of fermentation, should be quickly fired and well dried, which process ought not to exceed one hour. There is no doubt that quick packing after manufacture tends to keep a rich aroma in the teas, which it very soon loses on exposure even in a good factory. In many concerns it may be difficult to completely fire off the teas on the day of manufacture, but in all such cases they should be so far dried that there will be no danger of their getting so damp and soft as to risk the chance of sourness, which is apt to set in, if proper care is not taken.

The day's manufacture should be finished during daylight. With proper arrangements there should be difficulty in doing this. Manufacture carried on at night is always inferior. Of course there are times when this cannot be avoided, but this should be exceptional.

The roll should be spread less than 1 inch thick on the trays, and half an hour should be taken for firing. The malty quality in tea is imparted by brisk sharp firing. Teas should always have a final firing or hot sunning before packing.

Jackson's drier (we have not seen Kinmond's) completes the drying process in 15 minutes, and we suppose the perfection of preparation would be to pack hot. But as the various qualities have to be sifted and separated, a short final drying becomes necessary.

THE LABOUR QUESTION IN NORTH QUEENSLAND.

From the *Mackay Standard* we abridge the following account of a largely-attended meeting of the Planters and Farmers' Association recently held there:—

The President (Mr. Davidson) said that the object of the meeting was to consider the state of the labour supply in this district for plantation progress. Unless some great change took place it would be impossible to carry on the production of sugar at the profit due to large investments. There appeared to be three courses open to planters First, he was strongly in favour of getting coolies from India; of course, provided they came down under the most stringent regulations. For the present he thought there was little chance of getting the coolies, though he hoped that within a few years they would be introduced with the approval of the country. As for the plantations in which he was directly interested, no less than 350 kanakas would be returning from them during the current year, and he could not get more than 200 to supply their places. The result would be that he would have to reduce the extent of his cultivation unless he could obtain hands to do the work. Others, he knew, were similarly situated, and the result would be that the output of sugar for the district would be greatly diminished unless some provision was at once made to secure the labour required. The second proposition was to get Chinese. The planters would prefer any other class of labour, but the impossibility of procuring adequate supplies of kanakas, or of getting coolies, appeared to him to compel planters to avail themselves of any source of supply which might be open to them. He believed it would be found impossible to grow sugar profitably without at least one coloured labourer to every six acres of cane cultivation, and, at that rate, more men were required than appeared to be available. The third proposition was the purchase of a steamer to run to the islands. It was thought that many islands which could only be reached with difficulty by sailing vessels, could be tapped by the employment of a steamer, and that plenty of men would be procurable.

The following resolutions were then put and carried:—"That the association is of opinion that the purchase of a steamer is not desirable." "That it is desirable to procure a supply of Chinese labour on the basis of the letter before the meeting." "That Mr. J. M'Bryde be authorized to proceed to China with letters of credit and letters of introduction with a view of obtaining a supply of the labour if it appeared to him likely to be satisfactory."

A list was opened in the room of the names of those desirous of obtaining the Chinese, and applications for over 300 were at once made.—*Queenslander.*

[Our sentiments in regard to Chinese as estate labourers are well known. The bad characters amongst them are liable to sudden outbreaks in which they are reckless of life. The quiet and industrious are impatient to set up for themselves as market gardeners, shopkeepers and so forth. The continued success of the sugar industry in Northern Queensland depends on a well-ordered system of cooly immigration from India.—ED.]

REPORT ON THE GOVERNMENT CINCHONA ENTERPRIZE IN JAVA FOR THE 1ST QUARTER 1883.

The weather was very variable during the past quarter. At the end of February, as well as in the beginning and middle of March, a drought quite exceptional for those months was experienced, which was not favorable for the young plants. At Nagrak especially the young plants suffered greatly from the drought. At the end of January a severe storm was experienced everywhere. Of all the plantations the Nagrak establishment suffered most from it. Considerable damage was done not only to the plants but also to the dwellings and the nursery-house. The export of cinchona bark during the past quarter amounted to 98,247 Amst. lb. Of this 61,456 lb. belong to the harvest of 1882. Of the produce of the harvest of 1883 34,970 Amst. lb. are intended for sale in the Netherlands, and 1,821 lb. for the local military medical service here. There are still some 35,000 lb. of bark in the packing-houses, which on account of a larger supply of means of transport will at the end of this quarter be quickly dispatched to Tjikao. The supply of laborers was more than sufficient, in spite of the great demands for labor on the private cinchona estates, which are continually extending in the vicinity of the Government gardens. On 3rd March 2,000 Ledgeriana grafts were sold by public auction at Bandoeng. Of these 1,300 found buyers at the upset price of *f*10 each, fixed by the Government. The plants were bought solely by Java cinchona planters. According to the information given in the report for the 4th quarter of 1882, the fear was still entertained of the exercise of an evil influence of the succirubra stem on the Ledgeriana graft. An analysis of bark taken from twenty grafts obtained from slips of the mother tree No. 23 clearly evidenced the groundlessness of this fear. On examination of these three-year trees indeed not a trace of cinchonidine was discovered, while 7·37 per cent of quinine was found in the bark. Slips were therefore taken almost wholly from this wonderful tree for artificial propagation. At the beginning of March two years' leave to Europe was granted to the Director of the Government cinchona enterprize, J. C. Bernelot Moens. The Assistant Director was appointed to act for him. With reference to an Assistant Director, nothing had been determined at the end of this quarter.

VAN ROMUNDE,
Dir. Govt. Cinchona Enterprize.

Bandoeng, 8th April 1883.

THE BOILING OF WATER AND THE "RECEPTIVITY" OF CERTAIN ANIMAL (AND PLANT) CONSTITUTIONS.

We append an interesting and instructive paragraph from *Knowledge* written by Mr. W. Mattieu Williams in discussing "the chemistry of cookery." He says:—

"Our tea-kettles, engine boilers, &c., become incrusted when fed with calcareous waters, and most wat rs are calcareous; those supplied to London, which is surrounded by chalk, are largely so. Thus the boiling or cooking of such water effects a removal of its mineral impurities more or less completely. Other waters contain such mineral matter as salts of sodium and potassium. These are not removeable by mere boiling.

"Usually we have no very strong motive for removing either these or the dissolved carbonate of lime, or the atmospheric gases from water, but there is another class of impurities of serious importance. There are organic matters dissolved in all water that has run over land covered with vegetable growth, or, more especially, which has received contributions from sewers or any other form of house drainage. Such water supplies nutriment to those microscopic abominations, the *micrococci, bacilli, bacteria,* &c., which are now shown to be connected with blood-poisoning—possibly do the whole of the poisoning business. These little pests are harmless, and probably nutritious, when cooked, but in their raw and wriggling state are horribly prolific in the blood of people who are in certain states of what is called "receptivity." They (the bacteria, &c.) appear to be poisoned or somehow killed off by the digestive secretions of the blood of some people, and nourished luxuriantly in the blood of others. As nobody can be quite sure to which class he belongs, or may presently belong, or whether the water supplied to his household is free from blood-poisoning organisms, cooked water is a safer beverage than raw water.

"The requirement for this simple operation of cooking increases with the density of our population, which on reaching a certain degree renders the pollution of all water obtained from the ordinary sources almost inevitable.

"Reflecting on the subject, I have been struck with a curious fact that has hitherto escaped notice, viz., that in the country which over all others combines a very large population with a very small allowance of cleanliness, the ordinary drink of the people is boiled water flavoured by an infusion of leaves. These people, the Chinese, seem, in fact, to have been the inventors of boiled water beverages. Judging from travellers' accounts of the state of the rivers, rivulets, and general drainage and irrigation arrangements of China, its population could scarcely have reached its present density if Chinamen were drinkers of raw instead of cooked water."

Apart from what we are told as to the greater safety of cooked rather than raw water—and, in Ceylon, boiled water, filtered and cooled, is often a necessity and is especially desirable in the case of children;—the remark as to the 'receptivity' of the blood of certain people, an esteemed correspondent thinks, may throw light on the way in which certain coffee trees suffer from leaf disease while others close by are often exempt. The germs alluded to are "killed off" in some and luxuriantly nourished in others, *somehow*, but no one knows how. Now, it may be maintained that there is a *logical necessity* for the existence of such a 'certain state of receptivity' in the coffee tree, the greater or less degree of which determines the greater or less severity of the attack. Surely there is nothing extraordinary in this: any more than in the fact that certain plants refuse to grow in some soils and luxuriate in others. But then, did not Marshall Ward seem to deny any such state in our coffee trees, although in so doing he would appear to be opposed to both fact and theory?

A COORG COFFEE PLANTER IN AUSTRALIA.—Mr. R. Lindsay, late a coffee planter in Coorg, but now residing at Waldeck, Ballina, New South Wales, writes to us as follows:—"I was for ten years a coffee planter in Coorg, but sold out a year and a half ago, as the smallness of the money to be made in coffee did not compare favourably with the long residence to be made up country in India; so I packed up my traps and made 'tracks' for Australia. After looking about the colonies for six months, I decided to settle here in sugar planting and farming generally. This sugar growing ranks with sheep and cattle farming as a money-making concern, and is besides the very thing for men with small capital, say two or three thousand pounds, up to any amount. The climate here in the north-east corner of New South Wales, is the very thing for an Anglo-Indian, something like that of the Neilgherries, but with a sea breeze. Pine apples grow splendidly in the open air, and all other tropical fruits and flowers grow as well here as they do in the tropics, while the climate has not the same relaxing heat. Besides sugar cane and maize, my staple products, I have growing here bananas, pine-apples, passion fruit, custard-apple, lemons, oranges, peaches, guavas, grapes, figs, mulberries, water-melons, pumpkins, sweet potatoes and all English vegetables, and even the eternal Madras 'brinjal.'—*M. Mail.*

HOW TO ENJOY COFFEE.—It remains then to make the coffee. A common coffee-pot suffices, and the commonest kind of boiling water. We want no percolators or extractors; and, indeed, if this paper has any value, it will perhaps consist in the prescription of an exceedingly simple plan of ensuring coffee "as in Paris." Put into the pot a teacupful of coffee and two teaspoonfuls of chicory for every three breakfast cups of infusion required. Put the pot on the hot pate for a few moments to warm the coffee, then pour in the boiling water and put the pot on the fire, and when the coffee boils pour it out and return it a few times in the "old fashioned way," for the is no better way; and you want no egg shells, no sole skins, and no isinglass, for if you are smart in your movements, and then leave the pot alone for five minutes, the infusion will be as clear as an honest man's conscience and you have but to pour it out in the cups and enjoy it. Having made it, you must drink it; and here it must be recorded that as a breakfast beverage it is certainly better with hot than with cold milk. The why and the wherefore cannot be explained by the writer of this, but the fact is not to be doubted, that scalding the milk improves the flavour and the wholesomeness of the coffee. It should be strong, so as to require reducing with milk and sweetening with sugar, and then it is a question if it is not equivalent to meat and drink for assuredly it is as full of support as Atlas, who once took the earth upon his back and is said to have thought nothing of it. Conversing lately with a friend on this subject, he said that when in a Continental hotel he found it a very easy matter to conform to the Continental rule of eating only biscuit or light roll with his morning coffee, "For," said he, "there is so much support in their splendid coffee that I can do a long and heavy morning's work in picture galleries, and hard walking, and want nothing after my coffee and roll until I return at one to the substantial and savoury déjûnner At home I take tea with bacon and eggs, but I prefer the ontinental fashion of grand coffee and but little to eat with it." Those to whom, by reason of the day's engagements, it is a matter of importance to make a hearty breakfast, "coffee as in Paris," may be less desirable than appears. At all events, in our households, when we have any reason for beginning the day with a good meal, we take care to order coffee for breakfast. Taking a broad view of the subject, and with regard to health solely, it seems that tea is an impoverishing sort of beverage, and as a rule, not fit for regular use at the beginning of the day.—X. Y. Z. in the *Gardener's Magazine.*

CINCHONA CULTURE IN JAVA.—We call attention to the first report on the Java Government Cinchona Gardens written by Mr. Moens' successor, and translated for our columns. The most important fact is the complete success of the ledger grafts on succirubra stems, the red bark trees exercising no deleterious influence as was feared. Can it be true as stated by a visitor from Java that *one* private proprietor in that island has as many as 5,000 acres under Cinchona Ledgeriana and all flourishing and promising well? It seems rather a big story.

NOT CONTENT WITH MAKING COFFEE OUT OF DATE STONES, the inventive genius of the age promises to produce us cheese which has never seen the inside of a dairy. For a long time past, it appears the Chinese and Japanese have indulged, with much satisfaction, in a very remarkable kind of bean which grows in that region; but some energetic European has found out that this bean, owing to the greasy matter and the albumen which it contains, can be worked up into an excellent cheese. The bean is, therefore, to be imported into the south of France, and, if it thrive we are promised cheese which will rank with nothing less than the very best Parmesan.—*Rio News.*

THE PERTINACITY AND PREDOMINANCE OF WEEDS.—Considering weeds to be plants of the nature of herbs which tend to take prevalent possession of soil used for man's purposes, irrespective of his will, Professor Asa Gray inquires, in a recent paper in *Silliman's Journal*, whether weeds have any common characteristic which may give them advantage, and why most of the weeds of the United States, and probably of similar temperate countries, should be foreigners. This latter is strikingly the case on the Atlantic side of temperate North America, where the weeds have mainly come from Europe, and the common answer to the question must be largely true—viz., that, as the region was not really forest-clad, there were few of its native herbs which, if they could bear the exposure at all, could compete on cleared land with emigrants from the Old World. A certain number of the weeds in that region have come from the west and south, some with rather rapid strides in recent years owing to increased means of communication, and there are also native American weeds, indigenous to the region, which have become strongly aggressive through changed conditions. Professor Claypole, of Ohio, has tried to account for the predominance of Old World weeds in the Atlantic United States by supposing a greater "plasticity" in European than in American flora (the plant more easily adapting itself, if the change be not too great or sudden, to its new situation, and taking out a new lease of life as a weed). But Professor Gray regards this view as purely hypothetical. Again, Mr. Henslow thinks that weeds or intrusive dominant plants generally have a common characteristic to which this dominance may be attributed—viz., that they are in general self-fertilized plants. The question whether the weeds which Europe has given to North America are more self-fertilizing or less subject to cross fertilization than others is examined by Professor Gray, and he is led to answer that self-fertilization is neither the cause nor a perceptible cause of the prepotency referred to. A similar conclusion is justified by a cursory examination of the indigenous weeds of the Atlantic States, and of the prevalent species in California, which (as might be expected) are mostly indigenous species or immigrants from South America, though the common weeds of the Old World, especially of Southern Europe, are coming in.

GINGER-BEER.—Dr. Ondaatje, of Ceylon, states that the bark of *Vateria Indica*, or piney-tree, is constantly used by the Cingalese to arrest the alcoholic fermentation of the juice of the jaggery palm, which is a favourite beverage with them. This property of arresting fermentation might, perhaps, be used to keep ginger-beer sound, though more definite information as to the mode of use is desirable.—*The Chemist and Druggist.*

THE CLIMATE OF S. PAULO, the captital of the Santos coffee district, is thus summarized in the *Rio News*:—

ANNUAL SUMMARY.

Meteorological observations taken at Braz, in the city of S Paulo, during 1882, by the Companhia Cantareira e Esgotos:—
Lat. 23 deg. 32 min. 58 sec. S.
Long. 46 deg. 36 min. 46 sec. W. (Greenwich).
Height of barometer, 2,393 ft. above mean sea-level.
Do of rain-gauge, 2,378·5 ft. do do
Maximum pressure of barometer during hours of observation 27·991 inches on 10th June, 9 p m.
Minimum pressure of barometer during hours of observation 27·409 inches on the 8th December, 9 a m.
Maximum pressure of barometer during hours of observation corrected to 32 deg. F. at sea-level, 30·481 on 18th July, 9 p m.
Minimum pressure of barometer during hours of observation corrected to 32 deg. F. at sea-level, 29 671 on 6th July, 9 a m.
Maximum thermometer in shade 91 deg. 9 on November 27th.
Minimum do do 33 deg. on August 7th.
Do do on grass 26 deg. on August 5th.
Total rainfall during year 60·40 inches.
Greatest fall on one day 2·61 inches on January 4th.
It rained on 156 days.
Fog on mornings of 77 days and nights of 14.
Dew on mornings of 113 days and nights of 137.
Thunder and lightning on 40 days.
Thunder heard and lightning imperceptible on 29 days.
Lightning seen and thunder not heard on 31 days.
Lunar Coroua observed on January 31st, June 26th and 29th August 19th and December 18th.
Lunar Halo observed on May 30th, Nov. 21st and Dec. 21st.
Comet observed on 30th September.
Zodiacal light observed on August 13th.
Frosts on 10 nights.

THE FUELS OF INDIA: SUN HEAT.—In a series of lectures at Bombay by Mr. Alfred N. Pearson, a mining engineer, the following interesting statement was made:—

Under the heading of "Fuels," the coal fields of India were touched upon, and it was stated that India contained the thickest known coal seams of the world, some being 100, 120 and 160 feet thick. On the Raniganje coal field, which had a probable area of 1,000 square miles, there were in 1872 no less than 44 mines at work. In 1879 this field yielded 523,000 tons of coal, and gave employment to 389,000 men, 195,000 women, and 27,000 children. The expense of carriage of coal over land was very considerable and prevented the Indian coal fields from meeting much more than the local demand. Coal which in 1880 sold at 2½ to 3 rupees at the pit's mouth on the Raniganj coal field, cost 7 to 8 rupees in Calcutta and no less than R50 in Lahore. Mr. Ball, in his little book on the 'Diamonds, coal and gold of India,' stated that the annual consumption of coal in India was upwards of one and-a-half million tons, and that in round figures two-thirds of this amount was raised in the country. As a sign of progress in the development of Indian industries this statement was not unsatisfactory; but it was completely dwarfed when one turned to the statistics of the English coal fields where in 1872 not one and-a-half million, but 123¾ millions of tons of coal were raised, 16 millions of which were exported, and the rest consumed in the country. Other fuels, such as wood, peat, lignite, and petroleum were dealt with; and before leaving the subject of fuels the importance of the sun's heat as a fuel was pointed out. However unequally wood and coal were distributed over India, there was no doubt that sunshine was given impartially enough. Some efforts to use it in a concentrated form had been made in the drying of tea, but with only partial success. For the most chemical processes and even for brick-burning, the lecturer believed a determined effort to apply it would result in success.

NEW INDUSTRIES AND BONUSES.—The Colonial Secretary of New Zealand has been instructed to offer the following bonuses for the encouragement of new local industries:—Fifty per cent on the value realized for the first £1,000 worth of cocoons or silkworms' eggs produced in the Colony, to be paid on quantities of not less than £50 worth, or more than £100 worth, reared by any one person; £500 for the first £2,500 worth of native manganese and bronze; £300 for the first £1,500 worth of native marble sold in a foreign market for not less than 9s per cubic foot: £500 for the first 250 tons of native antimony regulus sold in a foreign country at a fair market value; and £1,000 for the production, from native ores by a direct process within the Colony, of 200 tons of "iron blooms" of marketable quality.—*Public Opinion.*

THE EMANCIPATION QUESTION IN BRAZIL is thus discussed by Mr. J. W. Hammond, in a letter to the *Rio News*:—

All revolutions leave blood stains; therefore the milder they are the less apparent will these be. In the Brazilian emancipation I, however, see so many and such fearful rocks and breakers ahead, that I should be truly glad if some one could point out the safe way. There are employed in the coffee plantations of Brazil about 500,000 slaves, of which, if freed, only about 150,000 would work, and these not so hard as they do now. Here therefore we find a want of 350,000 laborers, which would have to be found somewhere, to carry on the great agriculture of the country To supply this need only about 10 to 15,000 free people enter the plantations yearly, all other immigrants or free laborers finding the of a living in Brazil so easy near the large cities, where there are some diversions and pastimes, naturally prefer this, to the comparatively hard life in the preparation of coffee for the market. At this rate, it would take 20 years to supply the simple needs of the present plantations; but during those 20 years what would become of the Brazilian nation, as a nation, if it lost, say, only half of its revenue from coffee, a sum greater than £4,000,000 (four millions pounds sterling)? If it can be proved that no thought need be given to this point then will I join you, in calling out for immediate emancipation. That there will be troublous times, and grievous ones, if this question be not properly worked out, you yourself concur in, in saying that in the United States "they" (the emancipated ones) "went to work in part just as soon as the country became settled and returned to productive pursuits." Now if there had been no time of nonproduction, no time when the country became unsettled, hence returned to weeds and rank growth, there could not then have been a time of returning. This is the time I dread for Brazil, the days of non-production, of anarchy, and of misery, which will come between the abandoning of, and the returning to cultivation Surely the fact can not be contested, that the United States suffered horribly during the period, from the promulgation of forced emancipation in 1863 down to 1866—this was during the war and shortly after it, and the war was the payment for the holding of slaves. We must not hide the fact that great social upturnings bring tremendous social misery in their wake. The English paid hard cash, and the Americans slaughtered each other in order to bring about emancipation. Which of these would you have the Brazilians follow? The first they can not; the second would be the abandoning of the ills we know of, for those we know not of. Brazil must try other means, if she would attain an early and satisfactory emancipation, free from bloodshed and bankruptcy, and one which would bless the emancipated as well as the emancipators.

Correspondence.

To the Editor of the "Ceylon Observer."

EFFECTS OF *HEMILEIA VASTATRIX* ON COFFEE.

Coppah, 3rd May 1883.

DEAR SIR,—In your paper of the 14th ultimo, I notice a letter from "D. B. C." in reference to mine on the above subject. I agree with him about the effects on old trees, but not on the young. On the young, the leaves drop as they do on all trees attacked with the disease, but the branches do not necessarily die back, and why? Because, being young, there is more nourishment in the soil to enable the plants to survive easier than is the case with the old coffee. If I mistake not, it is the wind that spreads the *H. V.* by driving the seed of the fungus from one tree to another, and there it germinates and increases.

I am no botanist, but I presume that, to a great extent, the peel of the berry is of the same substance as the leaves, and, therefore, if the seed of the fungus germinates on the leaves why not on the peel, and if it does so germinate then the attacked peel has the same effect on the berry as the infected leaves have on the tree: that is to say, it feeds on the nourishment that would otherwise go to mature and ripen the berry and consequently weakens it.

The printer made an error in the signature of my last by mistaking the "E" for a "C."—Yours truly,

J. R. E.

CORRECTION IN DR. TRIMEN'S REPORT.

Ootacamund, 9th May 1883.

SIR,—I regret to find on p. 10 of my report for 1882, (see page 925 of *T. A.*) in the analysis of "hard Carthagena" bark, that a line has been omitted. The amount of cinchonine should be ·80 and there should follow it :—

Amorpheus... ·71

This makes the total 4·75, as printed. This analysis, with those of other varieties of Columbian bark will be found printed in the report by Robert Cross of his mission to South America in 1877-78, p. 53.

I am sorry that, in the hurry of leaving Colombo, I should have let this error escape me.—I am, yours faithfully, HENRY TRIMEN.

TEA-GROWING BY THE SEASIDE.

16th May 1883.

SIR,—Can you please inform me in your next issue whether tea will grow on estates lying close to the sea (say about one-eighth of a mile), and at no greater elevations than about twenty or thirty feet from the level of the sea? If indeed your answer is in the affirmative, then it may be well for coconut estate owners, who seldom receive a greater return than twenty rupees per acre a year, to become exclusively tea planters, when they will get a return of six times the amount they now get. I say, exclusively, because I think (under your correction) that tea will not grow with coconuts, under the shade of its palm. This, however, is not my object in seeking the present information from you. My object is to clear up a jungle lying close to the sea and to plant it with tea, if you recommend it. I shall also thank you to refer me in this your invaluable paper to some publication, whence I can obtain information respecting tea planting: especially of pruning, plucking and preparing tea.—I remain, yours truly,

LOWCOUNTRY.

[Tea is being successfully cultivated in the Kalutara district within the influence of the sea-air, though some miles distant and at an elevation of perhaps two or three hundred feet above it. An experiment even nearer and more on a level, would probably be successful provided the soil were good; but where is there good jungle and soil contiguous to the sea? The pamphlet published at this office "Tea-planting in Southern India and Ceylon" will give the information required by "Low-countr."—ED.]

SILK CULTURE IN CEYLON.

Hope Estate, Deltota, 20th May 1883.

DEAR SIR,—Of the cocoons I brought from England a great many hatched out on board the steamer and the moths paired freely. I have eggs of the following species now ready for distribution gratis to all who take an interest in sericulture:—*Cecropia, Polyphemus* and *Peruyi*. The worms of the first-mentioned feed on pear, apple, plum and other fruit trees, and the other two species are oak-feeders, and can doubtless be reared on loquat, Avocado pear and indigenous trees whose foliage is of similar character.

The moths of *Cynthia, Attacus ricini* and of the Himalayan *atlas* have not yet emerged.—Yours faithfully, P. N. B.

TEA-PLANTING.—Some time ago a Ceylon planter wrote to us:—While conversing this morning with a proprietor of tea estates in Cachai, I learned a practice in tea-planting there, which I have not seen brought forward in any of your articles on the subject, and which may be interesting, if you do not already know it. In planting it has become usual, in order to secure a first-class tea, to plant the following varieties and proportions in the same field:—First-class hybrid 75 per cent, pure indigenous 15 per cent, and China tea 10 per cent. On older fields, where this has not already been done, the planters are supplying with a view to arrive at it. [Has this ever been confirmed?—ED. C. O.] The China growth should be central and surrounded by the hybrid, while the indigenous is planted promiscuously throughout the field. I have also been told that all teas should be properly cured and packed *on the estates*, as any subsequent break of bulk causes deterioration.

CANKER.—A planter who has recently returned from a tour through the Dimbula and Dikoya districts writes us as follows:—Few people have any conception of the enormous number of cinchonas that have died during the last 12 months from canker and the large number that will very likely go during this present year. Even planters themselves object to discuss the question. There is no doubt in my mind that canker is spreading and that, rapidly. It is much more difficult now to grow plants than it used to be and it is well nigh impossible to get any large percentage to strike after planting out, whilst some say that pricking out beds that have once been used are unable to raise a plant. I confess I myself have not found this to be the case if the soil of the beds is loose and free. It used once to be thought that 18 months to two years old was the most critical time for a cinchona tree, but I think now all times and ages are critical, and none more so than another. I suppose a smaller percentage of trees of six year old have been raised from cinchona seed than from seed of any other tree in existence? How many seeds are there as an average in a lb. of succirubra seed—I suppose about 400,000. How many pounds weight of seed does each six year old tree represent!—Local "Times."

EXPOSING THE ROOTS OF FRUIT-TREES.

[The author of the following letter, it will be seen, is opposed to the Jaffna system of vine-culture, viz., exposing the roots.—ED.]

Regarding Jujube's comments on my remarks on exposing the roots of fruit trees, in the last number of the *Indian Forester*. The soil in his garden must be very good for the cultivation of vines. I find no difficulty here, in ripening the wood without having recourse to exposing their roots to sun and air, however my vines do not make a super-abundance of wood and I fancy his do. If he would reduce the amount of his wood by lopping off the leading shoots and thinning out the lateral ones periodically during their season of growth, he would not have to dig a trench round his vines in order to make them hibernate. By adopting that plan, I am certain he would obtain even better crops than at present. When vines are very luxuriant and produce more wood than they can ripen, it is better to cut it out as soon as made, than run the risk of injuring even a single fibre of their roots. Vines are very tenacious of life, and will stand very rough treatment for years, but the roots of those that have been least disturbed will remain in a bearing and healthy condition the longest.

Regarding his query as to the length of time a vine will live productively. This depends greatly on circumstances. If these are favourable it will live to a great age. The famous vine at Hampton Court was planted in 1769, and when last I heard of it (1878) was bearing a heavy crop. —W. G.—*Indian Forester*.

CACAO, LIBERIAN COFFEE, AND TEA GROWING ON THE OLDEST COFFEE ESTATES IN CEYLON.

The older cacaos in the lower fields ofthe estate (SINNAPITTIA) are very forward for their age, and will next year yield a fairish crop. The strong and vigorous growth of cacao in an old field of coffee, probably under cultivation for about 50 years, is really surpising. Anyone acquainted with hill cultivation, and who has seen the color of streams during a shower of rain, must have been sadly impressed with the sight of thousands of tons of valuable soil carried away to the sea with every rain-storm. Contour drainage, or even terracing, only tends to lessen wash, not to arrest it effectually. Well, I say those experienced in hill cultivation can quite understand the state of the soil of a field under cultivation for half a century, and subject to monthly scrapings and exposed to the rains of two monsoons annually. Plants growing in this field have nothing but subsoil to subsist upon, yet cacao is thriving apace. As cacao does not draw from the soil the same constituents as coffee, it may be said that the constituents it requires, never having been drawn upon, abound in the soil; but what explanation can be given of Liberian coffee not only growing in these fields, but flourishing with a vigour not to be surpassed even on virgin soil? About three years ago the plants put down amongst the old and washed out coffee, were bearing at such a rate, that the trees had to be supported with a dose of manure. The effect of the manure was to put on the trees a crop the branches were not able to support. They had all to be propped up with sticks and kept in position by strings drawn from the stem under *every* branch. The trees present a very ludicrous appearance now, with such a mass of rope on them. For some idea to be formed of the number of cherries a single tree has been bearing, I will quote from a letter in the *Tropical Agriculturist*, written evidently by the Superintendent, and therefore authentic:— "I picked off one Liberian coffee tree this morning 4,755 cherries. *** I am sorry I did not keep an account of what I picked in January. It was at least 3,000, and there are more than 4,000 more on the tree. Do you think any tree in Ceylon could beat this?" At the period of my visit the trees were enjoying a well-earned rest and had no crop on them to speak about, but they were looking far from played out, and seemed fit to bear many more large crops. The above has reference mainly to new products in fields of old coffee, but Sinnapittia has taken a new lease of life in its new clearing opened within the last three years. The traveller by train is introduced to these from the Gampola station onwards for over a mile. The land has a beautiful lie, and is composed of very fairish, porous soil. Most of the land was under heavy lantana when cleared. It is one continuous strip of about twelve chains in width, and running for very nearly 2 miles from end to end. These clearings, in extent about 150 acres, are planted with Liberian coffee and quincunxed with cacao. The growth of both products is very fair. I think the large quantity of loose boulders that are met frequently in the clearing, can be profitably utlized to terrace it. An ordinarily intelligent coolie can in a very short time be trained to masonry, and can with a coolie to assist it carrying stones, build from 100 to 120 feet a day. This is as cheap as draining and much more effective. Besides scattered as they are broadcast, the stones are very much in the way. These clearings of Liberian coffee and cacao are now being lined 4 × 4 and holed for tea.—"Examiner."

MR. VINCENT ON MADRAS AND ITS VAGETATION.

The gentleman who was deputed from India to report on the forests of Ceylon has given his impressions of Madras in the *Indian Forester*, in a letter from which we quote as follows:—

There can be no doubt that Madras is in process of becoming one of the handsomest towns in India. Were it not for its great area and want of local municipal funds, it would long ago have been undoubtedly one of the finest as it is one of the healthiest of them. A great feature in Madras is the number of large buildings, mostly public, built in the oriental style of architecture. Most prominent of all these is the Chepauk Palace, an old palace of the Nawabs of the Carnatic, largely added to, and now used by the Board of Revenue. Here I found the Forest office, with a fine verandah looking out to sea, over a pretty grass lawn adorned with fountains and young Poon trees. Near it is the grand new University Senate house, which seems to the uninitiated to be a mixture of Gothic and Saracenic architecture. Behind these and other neighbouring large buildings are the grounds of Government House, in process of transformation into a Botanic Garden, and a very pretty garden it will be when completed, for besides the sea frontage and the broad mouth of the Coom river, there are large tanks and the Buckingham Canal, pretty bridges and groups of trees of various kinds. The summer avenue trees of Madras are the Nim, the Casuarina and the *Odina Wodier*, the latter most remakable, as Dr. Brandis has pointed out, for retaining its leaves the whole year round, while only a few miles into the country it may be found in its usual cold weather leafless state. Hedges, principally of *Inga dulcis*, surround the large compounds of the houses, while in places groves of Coconut palms remind us of the first impressions of India we gained on landing in Ceylon. A special feature in Madras, and most of all in the more aristocratic quarters of Nangumbaukum, Chetput, Egmore and Adyar, is the immense size of the house compounds. Some of them would make a not inconsiderable park for an English squire, and the houses are generally large, airy and comfortable. The gardens seem to keep themselves; ferns and especially *Adianta* thrive most luxuriantly in the shade, while the magnificent growth of Crotons, which in Calcutta one is chiefly accustomed to see carefully tended in small pots, is in Madras a most striking feature, and makes gay the lawns and shrubberies with every shade of red and yellow and orange and purple. Here they are not small plants in small pots, but either in the ground direct, or in huge pots, they show tall masses of column often 10 to 15 feet high and proportionately broad. The great number of Nim [Margosa.—ED.] trees is very noticeable, while the yellow pods of *Albizzia Lebbek* keep up their ceaseless rattle at every puff of sea breeze which shakes the roadside trees. The public gardens, besides the new one which is being made near Government House, are the Peoples' Park and the Agri-Horticultural. The former, near the handsome Madras Railway Station, is not very well kept, and possesses very few trees of any size, but the latter has, though of small area, a particularly fine collection of trees and interesting plants. The curious *Kigelia pinnata* with spreading branches and huge pumpkin-like fruits hanging at the end of long strings from the branches attracts attention at once, and there is a Baobab which

gives a very good idea of what a strange object it must be in a Central African landscape. The Mahogany seems to thrive, and so do numerous species of Diospyros, while among the specimens of palms, are some which I do not remember even to have seen in the palm house or the palmetum at Calcutta. A rather longer excursion may be made to Guindy Park, which lies away to the west behind the model farm of Sydapet. Guindy Park is the hot weather residence of the Governor, and the shrubberies present specimen trees of almost everything curious that can be thought of. But to the Forester, there is nothing so interesting as the Casuarina, and indeed I expect that the Madras Presidency can, in its coast plantations of Casuarina, rival the work done on the dunes of Gascony with the maritime pine. But I must leave my remarks on them for another letter. A. V.

TROPICAL AGRICULTURE IN THE NORTHERN TERRITORY OF SOUTH AUSTRALIA.

On Friday evening, April 6, Mr. E. W. Price, Government Resident of the Northern Territory, who has just arrived in Adelaide on a holiday trip, delivered in the Town Hall Banqueting-room an interesting and instructive lecture upon "The Northern Territory, its climate, productions, capabilities and prospects." We quote:—Contrary to expectation agriculture could be carried on in the Northern Territory with success; fruit and vegetables were grown in various parts of the country from Palmerston to Pine Creek, and at all the telegraph stations the supply was ample. Having referred to the experimental garden under the care of Mr. Holtze, he stated that there were millions of acres of land far richer than that garden still open for selection. Speaking of the experiments with sugarcane, he expressed the opinion that the cane could be cultivated successfully without artificial irrigation or manure. Since then the cane had been tried on various other soils with equal success. The Chinese grew it for eating purposes, and on rich moist soil at Mindale, about one mile from the town, it attained great size, and the Chinese said it was very rich in saccharine matter. On the banks of the Daly River splendid cane had been raised. On the Adelaide River Mr. Sergison planted some on the virgin soil which was only ploughed a few days before for the first time. There the cane was growing splendidly, although the bush rats gave a little trouble, but that evil had disappeared. On Douglas' Peninsula, Messrs. Harris, Head, Errickson, and Clippenburg were growing magnificent cane on their farms, but too far away from the Delissa Company's mill to pay for crushing. Mr. Bean was growing some fine samples at Delissaville, but the ground at present cleared was in his (Mr. Price's) opinion not suitable. It was too light, and had not the power to retain sufficient moisture, except a small patch on the creek near the mill. No doubt on the same estate there were large patches of suitable land, but still uncleared. The same remark applied to the whole of that peninsula. He thought the great sugar estates of the Northern Territory would be on the banks of the rivers, and there were several reasons for that. First, the land was rich, and when cultivated turned into a rich loam—rich enough to crop for years without manure; secondly, there was no cost for clearing the land being ready for the plough at once; and thirdly, there was water carriage to the mill-door. The only disadvantage he could see was the rapid growth of grass, necessitating labour to keep it down. There were millions of acres of that rich land on the banks of the Daly, Adelaide, Victoria—the three alligator rivers—the Roper, Liverpool, and several smaller streams, so that the area as far as known in Queensland was limited; that in the Territory was practically unlimited. South Australia at present purchased 12,000 tons of sugar a year from other countries, every penny of which would remain in the country when the sugar industry was fairly developed in the Northern Territory. Immediate success could not be expected, nor had it been attained in Queensland without a great deal of difficulty, but that the Northern Territory climate was suitable for sugar-growing he had no doubt. The average rainfall in seven years had been 62 inches, spread over seven to eight months; and during the dry months at times heavy dews fell, quite as useful as rains, and at the Melbourne Exhibition some maize was shown which had been sown and reaped in the dry season without a single shower. There was one thing lacking in the Northern Territory, and that was lime, but the cost of supplying that would be small, as lime was easily obtained from shell and coral close to hand. The next interest in importance to sugar would be the cultivation of cinchona, but there was only one plantation of it yet, and Mr. Poett, who had taken it up, had great success promised him, although at first he had much trouble with the plants. Even in Ceylon Mr. Poett had not seen such rapid growth, and the great value of growing that plant was so well admitted that in Ceylon the coffee planters who had suitable land were trying cinchona, as being far safer and more remunerative than coffee. Liberian coffee succeeded very well, both at the Government Nursery and at Mr. Poett's place, where there were also 150,000 plants growing from seed cotton. Tobacco had to be planted at the Territory just at the close of the wet season, as the heat was too great before; it would therefore require irrigation, or a very moist and cool soil. Two fair crops had been produced at the Nursery, and cigars from it were exhibited at the Melbourne Exhibition. Indiarubber, a most valuable plant, was making rapid progress. Indigo, tapioca, arrowroot, rice, maize, ramie. (Chinese grasscloth), ground nut, sesame oil, and ginger—every one had been a perfect success. The plants that had failed were Arabian coffee, cinnamon, cocoa, nutmeg, pepper, tea, vanilla, and poppy. Many of those Mr. Holtze believed would succeed in moist gullies, but not close to the sea. The mangoe, breadfruit, custard apple, pineapple, soursop, orange, citron, lime, lemon, shaddock, banana, fig, peach, pomegranate, almond, quince, bambootam, and granadilla, as well as a large number of fodder plants, succeeded. As regarded the climate, he said that the Northern Territory for a tropical country was certainly healthy. There was no yellow fever, and as yet no cholera or smallpox. Dysentery was very rare; diphtheria was unknown, and so also was typhoid fever. The last question for intending planters was the labour question. He did not think the Chinese suitable for plantations. They were liable to leave at a very short notice, and perhaps when most wanted, while their wages—3s. a day—was too high. Therefore the Government had wisely provided for the importation of Indian coolies, who had everywhere proved themselves good plantation hands. They would supply every need in the labour line. In closing, Mr. Price spoke of the natural advantages of the Northern Territory, its various resources, the character of its buildings, fine harbours, admirable geographical position, and general advantages. He defended the Territory against its traducers, who were for the main part men whose ill-success was due to themselves; and he said that so far from the Territory now deserving the title of "White Elephant" it was a credit to South Australia and a valuable portion of her possessions. A hearty vote of thanks brought the engagement to a close.—*Adelaide Observer.*

INDIA:—CROP AND WEATHER REPORT.

FOR THE WEEK ENDING THE 8TH MAY 1883.

GENERAL REMARKS.—Heavy showers have again fallen in Assam, and good rain is also reported to have occurred throughout Bengal proper. In Madras rain has fallen more or less throughout the Presidency. In the Bombay Presidency heavy rain is reported from parts of Dharwar and slight showers from three other districts. In Mysore and Coorg rain has fallen in all districts. Elsewhere there has been no rain to report for the week under notice. No report has been received from British Burma

MADRAS.—No rain in Chingleput, Tanjore and Travancore; general prospects good.

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From LEWIS & PEAT's London Price Current, May 10th, 1883.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White	Slightly softish to good hard bright	£6
Yellow	Do. drossy & dark ditto	£5 a £6
CINCHONA BARK—		
Crown	Medium to fine Quill	2s a 3s
	Spoke shavings	1s 6d a 2s 6d
	Branch	1s 6d a 2s
,, Red	Medium to good Quill	1s 9d a 3s
	Spoke shavings	9d a 1s 9d
